Tabes Dorsalis.—Fifty of 200 neurosyphilitic patients had tabes dorsalis; 6 of these 50 had optic atrophy. The youngest was 8 years of age and the oldest was 55. All but 7 were males. Twenty-one patients had had some type of antisyphilitic treatment before coming under our care. Results of serologic tests of the blood

29. Hereinafter when we speak of "previous therapy" we will mean "antisyphilitic treatment administered prior to the patient's coming under our care." Almost invariably this treatment was inadequate, according to present day standards; that is, it had consisted of less than thirty intravenous injections of arsphenamine and six intramuscular injections of a heavy metal. Many of these patients had previously received only oral medication with mercury or iodides.

of 8 patients who had received no previous treatment were negative when the patients were first seen, and results of such tests of 6 patients who had received previous antisyphilitic treatment were negative when the patients were first seen. At the end of our treatment and observation period, reactions to serologic tests of the blood of 36 patients were negative, whereas such reactions concerning 14 patients were still positive.

Seven persons had group III spinal fluid, 33 had group II fluid and 10 had group I fluid. By virtue of the use of all types of treatment at our command, at the end of treatment and observation reactions to tests of the spinal fluid of 40 patients became negative, whereas such reactions among 10 patients were still positive (in all the fluid was of group I). Thirty patients received routine and intraspinal treatment alone; the spinal fluids of 26 patients became normal and reactions to tests of the spinal fluid of 4 patients remained positive. Condition of the spinal fluid relapsed in 5 instances, but in each of these instances the spinal

fluid became normal with further treatment of the patients, 3 of whom received malaria therapy and 2 of whom received Swift-Ellis treatment only.

Of the 19 patients who received malaria treatment plus intraspinal therapy, 5 still had spinal fluid which reacted positively to tests.

Only 2 patients in this particular group received tryparsamide; 1 received it alone with intraspinal treatment and 1 received it with both malaria therapy and intraspinal treatment. Nineteen patients received malaria treatment, 3 because of relapse of reactions to serologic tests, 2 because of clinical progression of the disease, 1 because of reactions from intraspinal treatment, 6 because the condition of the spinal fluid failed to respond and 5 because intraspinal treatment gave neither clinical progression nor improvement. For 2 of these 19 patients treatment had been started with fever produced by means of malaria. In the 2 cases in which clinical progression of the disease occurred, the condition in both became clinically arrested with the addition of malaria therapy. Of the 5 patients who did not respond to treatment, 3 remained in the same condition, 1 improved remarkably and 1 improved slightly.

In the group of 30 patients who received routine treatment plus intraspinal treatment alone there was no progression of symptoms, subjectively or objectively, whereas 24 of these patients obtained decided improvement; 20 4 obtained slight improvements and 2 exhibited no change.

30. This is considered as constituting subjective improvement manifested by the patient and expressed by him and noted by improvement in somatic complaints, gain of weight, improved appearance and sense of well being. Neurologic signs (objective symptoms), such as pupillary and other changes in reflexes, sense of position and pain, did not change with the patients under antisyphilitic treatment and observation.

However, when intraspinal treatment in the whole group of 50 patients failed to produce satisfactory clinical results, the use of other types of supplementary treatment such as malaria therapy and/or tryparsamide produced for 31 patients decided improvement in subjective signs and symptoms, slight improvement in such signs for 13 and no improvement for 6. The condition of no patient progressed.

Six of the 50 patients had optic atrophy in addition to other signs and symptoms of tabes dorsalis. For 2 of these 6 patients the type of antisyphilitic treatment first used was malaria therapy; 2 of the 6 showed progression of optic atrophy under intraspinal treatment and received malaria therapy in an effort to halt this progression. Two of the 6 patients had no further loss of vision on receiving routine and intraspinal therapy.

For only 4 tabetic patients did the spinal fluid become normal in less than a year. The longest period required for a positive reaction to revert to negative was eight years; this period was required for 3 patients. In the majority of cases the reactions to tests of the fluid became negative in one year to three years.

One patient received less than three intraspinal treatments. The remaining 49 patients suffering from tabes dorsalis received a total of three hundred and ninety-one such treatments, an average of about eight per patient.

Dementia Paralytica.—Thirty-four of these 200 neurosyphilitic patients had dementia paralytica, and of these 34, 13 had received previous antisyphilitic treatment. Generally dementia paralytica encountered among these patients was in a very early stage, and although many of them were euphoric and had grandiose ideas, in none was the condition in a vegetative stage. The youngest patient was 10 years old and the oldest was 53 years old. There were 2 women in this group. One patient had not received previous treatment and was found to have negative reactions to serologic tests of the blood. In 1 case reactions to serologic tests of the blood were negative, the patient having had previous treatment. Eleven patients still had positive reactions to serologic tests of the blood after treatment and an observation period of five years or longer.

Twenty-five patients had cerebrospinal fluid of group III, 8 had fluid of group II and 1 had fluid of group I on admission; at the end of our treatment and observation, 23 had normal spinal fluid, 9 had fluid of group I and 2 still had fluid of group III.

Among the 23 cases in which reactions to tests of the spinal fluid reverted to negative, in only 1 did the reaction revert to negative in less than a year; the spinal fluid of 2 persons became normal in one to two years; in 15 cases from two to five years were required for the reactions to reverse, and in 5 cases five years or more were required for the reactions to become negative. The longest period required for the fluid to become normal was thirteen years.

In 4 cases the reactions to tests of the spinal fluid relapsed; in 3 cases the reactions reverted to negative with further treatment of the patients, and in these three cases fever treatment with malaria was administered because of the relapse.

It is difficult to appraise the value of intraspinal therapy in this particular group of patients because of the fact that 16 patients also received malaria therapy and intraspinal treatment. 1 received treatment with tryparsamide and intraspinal therapy and 14 received therapy with both malaria and tryparsamide in addition to intraspinal treatment. Only 3 patients received intraspinal treatment and routine treatment alone, of whom

2 were decidedly improved and one was slightly improved. Thirteen others received the Swift-Ellis treatment before the institution of other methods of treatment. Three of these 13 patients received other types of therapy because of relapse of the reactions to tests of the spinal fluid; 10 of these 13 patients received other therapy because of failure of improvement as manifested by either reactions to serologic tests or remission of clinical symptoms. In 2 cases the disease showed evidence of clinical progression on intraspinal treatment of the patients but improvement was obtained with malaria therapy.

For 17 patients the first treatment administered was malaria, and 1 received tryparsamide. Follow-up therapy consisted of intraspinal treatment or administration of tryparsamide, or both. Of 11 who received malaria therapy first, plus intraspinal and routine treatment alone, 8 were decidedly improved, 2 were slightly improved and 1 became worse. Of 14 patients who received malaria therapy, followed by intraspinal treatment plus therapy with tryparsamide, 8 patients were decidedly improved, 4 were slightly improved and 2 became worse.

With all types of treatment, 22 patients were decidedly improved, 9 were slightly improved and 3 became worse.

Two patients received only one intraspinal treatment each; the largest number of treatments received by any 1 patient was thirty-nine. A total of three hundred and fourteen injections were made for 32 patients, an average of nine and eight-tenths injections each.

Meningeal Neurosyphilis.—Thirty-nine patients out of the series of 200 had meningeal neurosyphilis; the youngest of these was 21 years old and the oldest was 60 years old. All but 5 were men. Twelve had received previous antisyphilitic treatment before they came under our care. Two patients who had negative reactions to serologic tests of the blood had received no previous treatment, and 1 patient who had negative reactions to

fluid of group III was present and malaria therapy was administered without complete reversal of the condition of the spinal fluid; the other patient showed no improvement whatever in the condition of the spinal fluid, although results of serologic tests of the blood

did become negative. The patient showed no progression of symptoms in an eight year treatment and observation period.

Of 36 instances in which the spinal fluid became normal, the fluid in 21 became normal within a year or less, in 8 instances the fluid became normal within the one to two year period and in the other 7 instances the fluid became normal in the two to five year period. In 2 instances reactions to tests of spinal fluid relapsed to positive; in both the reactions became negative again and remained so. One relapse occurred in an uncooperative patient, the other in a patient whose reactions had relapsed twice and who, at the second relapse, received malaria treatment. None of the patients received tryparsamide, but 8 received malaria therapy or typhoid vaccine. One patient received malaria therapy first of all because his spinal fluid was found to be of group III. All but 2 of the remaining 7 patients (of the 8 who received malaria therapy or vaccine) had obtained decided clinical improvement before we proceeded with fever therapy; the sixth patient showed improvement only after the addition of typhoid vaccine to the therapeutic armamentarium, whereas the seventh patient showed no improvement after any type of therapy; this particular patient had convulsions, and it is questionable how much of a part the syphilis had in the production of the condition. Intraspinal therapy used alone or administered before other methods of therapy accounted for thirty-four decided improvements and for two slight improvements. There were no clinical data in 1 case.

No patient in this group of 39 received less than three intraspinal treatments, and the most received by 1 person was thirteen. There was a total of three hundred and thirteen Swift-Ellis treatments, or an average of about eight treatments per patient.

Tabetic Dementia Paralytica; Vascular and Meningovascular Neurosyphilis.—In this series 19 had the tabetic form of dementia paralytica, 2 had vascular neurosyphilis and 24 had the meningovascular form of neurosyphilis, a total of 45 patients. The ages varied between 4 and 55 years, and only 8 of the 45 patients were women. Seven patients had negative reactions to serologic tests of the blood, and all but 2 of these 7 patients had undergone previous treatment. After

* Partial overlapping of percentages with those in column headed "complete reversal."

serologic tests of the blood had received previous treatment. Under treatment, reactions to serologic tests of the blood became negative in all but 3 cases.

All reactions to tests of spinal fluid were positive. The fluid in 9 cases was of group III, in 1 it was of group I and in the remaining 29 cases it was of group II. In all but 3 of the cases reactions to tests of the spinal fluid became negative during the five year period of treatment and observation. In 2 of these 3 cases spinal

treatment and observation by us, all but 6 patients had negative reactions to serologic tests of the blood. Twenty of the 45 patients in this group had received previous antisyphilitic treatment.

In 15 cases the spinal fluid was classified as being of group III, 27 patients had spinal fluid of group II and 3 had spinal fluid of group I.

In 34 cases the spinal fluid became normal under treatment and observation; in the majority of these cases the fluid became normal within one and three years. In 23 cases the fluid became normal with the use of routine and intraspinal treatment alone, and in 11 cases the addition of malaria or tryparsamide therapy or both to the routine and intraspinal routine of treatment accomplished this result. In 11 cases reactions to tests of the spinal fluid remained positive; 8 of the 11 patients received fever treatment with malaria, 2 received therapy with tryparsamide and 1 patient received only routine and intraspinal treatment.

In 8 cases the condition of the spinal fluid relapsed; reactions in 7 of these cases reverted again to negative with further treatment, in 3 of these the reactions became negative when further intraspinal treatment alone was given, in 3 cases the reactions became negative with the addition of malaria treatment to the schedule of therapy, and in 1 instance of relapse after the use of both intraspinal treatment and malaria treatment, the reactions became negative with therapy with tryparsamide and typhoid vaccine.

Well defined clinical improvement was obtained for 18 patients who received routine and intraspinal treatment alone, whereas 4 patients showed slight improvement and 2 patients exhibited neither progression of symptoms nor improvement. Of 19 patients who received malaria therapy, 11 received it because intraspinal treatment had failed either clinically (6 patients) or serologically (5 patients); the other 8 patients, however, exhibited varying degrees of improvement before malaria therapy was employed (6 patients exhibited decided improvement and 2 improved slightly). Of the 2 patients who received intraspinal treatment plus tryparsamide, 1 showed much improvement and 1 slight improvement before tryparsamide was administered. With all types of treatment, 28 patients were decidedly improved, 11 were slightly improved, 5 showed no change and the condition of 1 patient progressed.

Only 1 patient received less than three intraspinal treatments, whereas the largest number administered to any patient was fifteen. The remaining 44 patients (of the 45 in this group) received a total of three hundred and eighty-one treatments, an average of eight and two-tenths Swift-Ellis treatments per patient.

Tables 2 and 3 show the results obtained clinically and serologically by intraspinal treatment before addition of the other therapeutic measures of malaria, typhoid vaccine and/or tryparsamide.

In table 4 the serologic and clinical results obtained from routine treatment only by the Cooperative Clinical Group are listed. These results should be compared with the results in our cases obtained by a combination of intraspinal and routine treatment, as set forth in tables 2 and 3.

COMMENT

A rather characteristic trend was noted of the condition of the cerebrospinal fluid of patients who subsequently exhibited improvement from intraspinal therapy. The first indication of benefit was found in the rapid

diminution of the cell count, although not uncommonly after the first intraspinal treatment there was a slight increase in this count denoting meningeal irritation. With subsequent treatment, however, this increase was noted only occasionally. In many instances, especially in cases of meningeal, asymptomatic, meningovascular neurosyphilis and in tabes dorsalis, the cell count was within normal limits at the end of the first course of intraspinal treatment. Because of the lability and sensitivity of the cell count of the cerebrospinal fluid, a decrease of the cell count of the fluid is a helpful prognostic guide in forecasting the subsequent changes of the spinal fluid after intraspinal treatment.

Next in order of responsiveness to intraspinal treatment was the flattening of the colloidal gold or colloidal benzoin curves (table 1). This sign of improvement, however, frequently lagged behind improvement as denoted in the cell count for from months to several years, whereas changes signifying improvement in results of the globulin and Wassermann tests were the last to appear. The latter two factors closely paralleled each other.

The value of classification of observations concerning the spinal fluid into three groups was further substantiated by this study. Patients with fluid of group I or group II generally do well under intraspinal therapy, whereas those who have fluid of group III have a tendency to be resistant to all but the combination of nonspecific and specific remedies. Dementia paralytica, which is accompanied by the highest percentage of cerebrospinal fluid of group III, is resistant to Swift-Ellis therapy. However, as brought out by the Cooperative Clinical Group, meningeal neurosyphilitic persons who have fluid of group III respond more readily than do patients with dementia paralytica who have a similar type of cerebrospinal fluid.

In general, the shorter the duration of neurosyphilitic symptoms the more rapid the response to intraspinal therapy was found to be. This trend did not necessarily pertain to the duration of syphilis, because those patients among whom neurosyphilitic symptoms developed early in the course of their disease often were resistant to all forms of treatment.

Certain valid criticisms may be made of a paper of the type of this one. First is the fact that an adequate series of control cases is lacking. The ideal method would be to start routine treatment alone for a large number of patients suffering from neurosyphilis and then to begin routine treatment plus one type of supplemental therapy for another similar group of patients for purposes of subsequent statistical study. It was obviously impossible to utilize such a procedure for a retrospective survey such as this one. Another criticism which may be brought forth by the opponents of intraspinal therapy is the assumption that other methods such as spinal drainage alone, or the introduction of unarsphenaminized serum, do as much good as the therapy we have described. Our answer to this is that in our experience such methods of treatment produced results, both clinical and serologic, which were inferior to those obtained with the Swift-Ellis technic.

In the present paper a selected group of neurosyphilitic patients were considered, namely those who were physically able to undergo intraspinal treatment because signs and symptoms of advanced phases of the disease had not been produced. In other words, intra-

spinal therapy was confined to patients who exhibited the early clinical signs of involvement of the central nervous system.

The fact that we have chosen patients who underwent treatment and observation for periods of five years or longer tends automatically to exclude many of the poor results obtained for patients with dementia paralytica and patients with the tabetic form of dementia paralytica, since these particular patients frequently die within five years after the onset of symptoms; on the other hand, many of the good results obtained for patients who had asymptomatic or meningeal neurosyphilis are excluded, since such patients disappeared from observation within this period.

The best results of intraspinal therapy were obtained for those neurosyphilitic patients who had the meningeal, asymptomatic and early tabetic manifestations of the disease. Patients who had early tabes dorsalis did decidedly better than those who exhibited signs of the advanced disease.

The poorest results were obtained for patients who had dementia paralytica. In the presence of this condition the main value of intraspinal treatment lies in postmalaria therapy if pronounced mental deterioration is not present. Intraspinal therapy is of less value than fever therapy and tryparsamide in the treatment of dementia paralytica.

The Swift-Ellis technic of intraspinal therapy in the management of some of the early manifestations of neurosyphilis is safe and the benefits gained from it by the patient far outweigh the incidence of untoward reactions to the procedure. In the present series there were only nine disturbing or potentially serious reactions in more than two thousand three hundred intraspinal treatments, and among none of these patients did permanent sequelae develop. The majority of these reactions were encountered by patients who had tabes dorsalis with evidence of involvement of the lower part of the spinal cord.

It is our opinion that treatment with malaria is more beneficial than Swift-Ellis therapy in producing arrest of the advancement of optic atrophy.

CONCLUSIONS

The indications for intraspinal (Swift-Ellis) treatment, provided the patient is in good physical condition and can tolerate the arsphenamines, may be summarized briefly as follows:

1. It is particularly of benefit for patients who have asymptomatic and meningeal neurosyphilis and for those who have early tabes dorsalis.

2. Intraspinal therapy of the Swift-Ellis type is of special value for patients who have the early manifestations of neurosyphilis when a trial with routine treatment has failed to produce clinical or serologic improvement.

3. The Swift-Ellis procedure is valuable postmalaria therapy in certain forms of neurosyphilis in which mental changes are not present.

4. When this procedure is employed, so-called foreign arsphenaminized serum may be used in cases of syphilitic cardiovascular disease with complicating neurosyphilis.

5. When the Swift-Ellis procedure is employed, a minimum of seven intraspinal treatments combined with routine therapy is desirable, although many patients do well with fewer treatments.

Contraindications to intraspinal therapy include, besides those common to the use of arsphenamine, the following: (1) patients who exhibit the clinical signs of neurosyphilis which persist in spite of adequate treatment in whom reactions to tests of the cerebrospinal fluid have become negative, (2) patients physically unfit, such as those who have advanced tabes dorsalis, (3) the presence of the signs and symptoms of advanced involvement and degeneration of the lower part of the spinal cord and (4) cases in which reactions from the treatment are more severe than those resulting from ordinary lumbar puncture.

Excellent serologic and clinical results may be obtained with treatment by a combination of intraspinal and routine therapy for patients who have certain forms of neurosyphilis. However, it is our practice to use other forms of supplemental treatment, such as fever therapy and/or tryparsamide, when satisfactory results fail to appear after a trial with intraspinal therapy.

ABSTRACT OF DISCUSSION

DR. HAROLD N. COLE, Cleveland: Drs. Kierland and O'Leary have brought out a fact that may not be well known, namely that it was Marinesco who in 1910 and 1911 first injected the serum of syphilitic patients into the same patients intradurally. Much has been written on the subject, though particularly in a period up to fifteen years ago. I wonder whether this has any significance. The writers' material is based on 2,369 intraspinal treatments given to 370 patients through the years 1924 to 1927, thus allowing prolonged follow-up study. There were reactions after 229 treatments, an incidence of 9.7 per cent, but the reaction after 200 of the 229 consisted of headache, nausea and vomiting and increased pain in the legs. The severe reactions were found more in persons with tabes dorsalis. In 5 of these they involved the bladder. In 2 transitory transverse myelitis developed, though 1 of them subsequently received further treatment without disturbance. In 1 there was meningitis, with recovery within three weeks. The results of therapy are limited to 200 patients observed for five years or more. The authors divide the evidence of neurosyphilis in the cases into asymptomatic manifestations, tabes dorsalis, the tabetic form of dementia paralytica, dementia paralytica and meningeal and meningovascular manifestations. Best results were achieved in cases of early involvement of the central nervous system—in cases of asymptomatic, meningovascular and meningeal neurosyphilis and of early tabes dorsalis. Poorer results naturally were obtained in cases of the tabetic form of dementia paralytica and of dementia paralytica. In 178 of the 200 cases treatment was started with a combination of routine and intraspinal therapy, and if there was no response then other measures were employed, particularly malaria therapy and treatment with tryparsamide. As must be expected, results in the treatment of syphilis of the central nervous system are measured in terms not of months but of years. Thus in only 4 patients with tabes dorsalis was there reversal of the condition of the spinal fluid to normal in less than a year. The longest period was eight years, and for the majority the period was one to three years. In cases of dementia paralytica the reactions were even more stubborn, and the longest period to reversal was thirteen years. Naturally it was not possible to achieve even this in all cases. Unfortunately, the authors have not found it possible to compare with other forms of therapy the treatment of a group of patients with syphilis of the central nervous system given routine and intraspinal therapy alone. Only such a report will really give an opportunity properly to evaluate its worth.

DR. HARRY M. ROBINSON, Baltimore: I am convinced of the usefulness of this method of treatment of syphilis of the central nervous system. During the early period of the use of intraspinal therapy I used this form, with serum, for almost all phases of syphilis of the central nervous system. As the

years rolled on, I gradually eliminated its use for all forms except *tubes dorsalis* and optic atrophy, as I had no good results with this treatment in cases of dementia paralytica. In cases of syphilis of the meningeal type my best results have been with the ordinary routine courses of injections of an arsenical of the arsphenamine group and a bismuth compound. I have had far better results with that than I have with intraspinal therapy. As a rule I prefer, when physical conditions permit, fever therapy in cases of uncomplicated syphilis of the central nervous system. I get much better results with that than with any other form of therapy. I believe, however, that it is preferable to start treating a patient with asymptomatic neurosyphilis with arsphenamine and a bismuth compound rather than to subject him to intraspinal therapy or fever therapy. If after a year or so there is not sufficient response one may resort to more strenuous forms of therapy. I would like to ask the authors a question which Dr. Cole mentioned. Has there been a control series of patients with syphilis of the meningeal type given just routine therapy, as it is commonly known?

DR. S. W. BECKER, Chicago: During the years that these patients were being treated I had the pleasure of administering the treatment to a great many of them. I can vouch for the efficacy of the form of therapy. When I went to the University of Chicago it was not possible to install the elaborate equipment necessary to administer intraspinal treatment safely, so that we had to try something else. We devised a method whereby after the initial treatment with sodium iodide given intravenously and soluble bismuth given six days a week for a few weeks we treated the patients, depending on whether they had early or late neurosyphilis, according to the base line schedule for the type of syphilis. After they had completed the arsphenamine phase of the therapy, instead of tapering the treatment off slowly, as is our custom, we gave these patients full doses of a bismuth compound in courses of ten weeks, only two months apart. We continued that therapy, sometimes for several years, until the reaction of the spinal fluid became negative. In an analysis of the results of this type of treatment prepared by Dr. Walsh and me and published in *THE JOURNAL*, Feb. 8, 1941, we found that our results were practically the same as those obtained by the Cooperative Clinical Group in the treatment of neurosyphilis. However, for our patients we had used collateral measures, such as fever therapy and the administration of trypanamide in a small proportion, perhaps 15 per cent, as compared with something like 65 per cent for the patients of the Cooperative Clinical Group. We feel that this type of therapy is safe, convenient for the patient and apparently as efficacious as some of the more complicated types, but it must be carried out over a long period.

DR. A. BENSON CANNON, New York: I have been using this method of treatment of neurosyphilis since 1914. The more experience I have with it the more convinced I am of its value; in carefully selected cases no other treatment can supplant it. Sometimes in a case of neurosyphilis of six months' or a year's duration in which the reaction of spinal fluid has become positive only one or at the most two or three injections of serum are required to bring the reaction back to negative; thus the amount and number of doses of arsphenamine required in the subsequent period of treatment will be appreciably reduced. As to what Dr. Cole has said concerning the complicated technic of the Swift-Ellis method, I believe that the more experience one has with this treatment the more one can simplify it and that it can in reality be made an uncomplicated routine technic. One simplification which I have used for years is to allow the patient to go home at any time from fifteen minutes to an hour after he has had the puncture. My associates and I find that by thus making the routine puncture a simple procedure of examination we are able to obtain consent to puncture many more times than we could before we adopted this practice. This is particularly true in the clinic, where we now get consent to a spinal puncture when desired in practically 100 per cent of cases, compared to about 35 per cent previously. Another simplification I have adopted is in the manner of giving the intraspinal treatment itself. Whether it is given in the office or in the clinic I allow the patient to go home at any

time from half an hour to two hours after the injection. I have never observed any serious accidents resulting from this practice. If the patients are carefully selected for this type of treatment it is safe to give the intraspinal injection in this fashion, thus doing away with the inconvenience to the patient of overnight hospitalization. One is accustomed to think of the spinal fluid as being more resistant to this type of treatment than the blood. As a matter of fact the reverse is frequently the case: giving intraspinal therapy to a patient whose blood and spinal fluid both show a strongly positive reaction will often render the reaction of the spinal fluid negative long before it has any effect at all on the blood.

DR. ROBERT R. KIERLAND, Rochester, Minn.: It must be remembered that no ideal system of treating syphilis of the central nervous system exists. This brings up the point brought out by Drs. Cole and Robinson regarding a control series. Unfortunately, few studies of any type of syphilis have adequate controls. Perhaps the only study which may be considered as such is that by Brusgaard. The ideal system would be to take 100 consecutive patients with neurosyphilis and treat them with nothing but the routine type of therapy in spite of what good or bad results may have been obtained. An additional hundred neurosyphilitic patients should receive nothing but a combination of intraspinal treatment plus routine therapy, the next hundred should receive trypanamide, the next hundred fever therapy and so on. This is manifestly impossible, as when one treats private patients one tries to obtain the best results possible with a combination of all types of therapeutic measures. It must be remembered that in the majority of instances patients who were started on a routine therapy received no other type of therapy if they obtained good results. The same practice applied to intraspinal treatment. If while receiving a combination of routine and intraspinal treatment they obtained good results, other supplemental procedures were not used. The reason that many patients received these supplemental forms of treatment was that they did not do well with the type of therapy previously given. I think that will serve to clear up the remarks of Dr. Robinson. The results pictured on the slides are only those obtained before the institution of other therapeutic methods, and the complete paper will include also the final results obtained with all types of therapy. I am familiar with Dr. Becker's and Dr. Walsh's work concerning the prolonged use of bismuth compounds but have had no experience with it. If these studies are confirmed, it is a large advance in the treatment of syphilis of the central nervous system. I hardly agree with Dr. Robinson's remark that routine treatment alone does better than a combination of intraspinal and routine therapy. Certainly that is far from the experience of the Cooperative Clinical Group. This is borne out in practically all their studies, particularly the last three dealing with asymptomatic neurosyphilis, *tubes dorsalis* and the complete paper on symptomatic neurosyphilis.

The Plight of the Best.—Five years after graduation the ablest of my contemporaries were making \$10,000 a year in practice and have continued at that level or above it. The equally able men who went into teaching or research were at \$3,000 after six years and a few have worked up to \$9,500 twenty years later. It may be replied that low salaries eliminate the incompetent. They do not. I may as well say straight out that the incompetents stick on. Low salaries may cause the money minded and the hard pressed to go elsewhere. The worst and the best stay on. One cannot pass over the incompetents as negligible. They clog the roads. But the plight of the best is truly distressing. Indeed, I could offer no excuses for what I know, but cannot reveal, regarding the struggles of some of the most eminent medical scientists in this rich country to raise and educate their none too numerous families. If you detect indignation in these remarks please remember that the best investigators in medicine are men of humility and modesty who do not know how to protect themselves in serving our highly competitive society. That seems to me society's loss and its shame.—Gregg, Alan: *The Furtherance of Medical Research*, New Haven, Conn., Yale University Press, 1941.

ACUTE HEMATOGENOUS STAPHYLO-
COCCIC OSTEOMYELITISTREATMENT WITH SULFATHIAZOLE WITHOUT
OPERATION

WALTER A. HOYT, M.D.

ADRIAN E. DAVIS, M.D.

AND

GEORGE VAN BUREN, M.D.

AKRON, OHIO

Sulfathiazole, with its bacteriostatic and bactericidal properties, offers a new approach to the treatment of acute staphylococcic osteomyelitis by attacking the staphylococcus organism both in the blood stream and in the local lesion.

Up to the advent of sulfathiazole the treatment of the bacteremia or the toxemia has been directed toward supportive methods, such as infusions, blood transfusions and the use of antitoxins, as advocated by Baker and Shands¹ and other investigators. The universally accepted approach to the local lesion has been operative, varying from simple incision and drainage of the soft tissue abscess to more radical drilling or guttering of the bone. Authors are divided as to the extent and time of operation. One school, represented by such men as Hart,² Fraser,³ Robertson⁴ and Conwell and Sherrill,⁵ advocates early incision of both bone and soft tissue. Another school advocates delayed operation and then only incision and drainage of the soft tissue (Wilensky,⁶ Crossan,⁷ Green and Shannon⁸ and others). Both schools, however, have expressed the belief that some type of drainage is necessary. Attempts to combat the staphylococcus organism locally once drainage has been established have met with little success.

A review of studies of the end result of both acute and chronic osteomyelitis, regardless of the methods of treatment employed, is conclusive evidence of the inadequacy of the usual treatment of the disease. The high mortality, long hospitalization, severe deformities, secondary joint involvement, multiple operative procedures, economic loss and invalidism are grim monuments to this fact. Crossan⁹ in 1938 made an excellent survey of all the literature on osteomyelitis for a seven and one-half year period and concluded that one fact was established clearly and one fact only; namely, the disease has a poor prognosis. Slightly more than one-fifth of the patients died and nearly two fifths of the survivors were crippled. Some of those not crippled were invalids or suffered periods of recurrent invalidism because of the disease.

From the Children's Hospital.

Read before the Section on Orthopedic Surgery at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

In the recent literature there has been a definite trend toward conservative treatment, and the following significant observations have justified this conservatism. Early operation has increased toxicity, and negative blood cultures have become positive (Dolman¹⁰). The mortality appears to be greater among patients on whom operation is done early, especially when bone is opened (Pyrall and Pain¹¹). Early operation does not appear to lessen the extent of involvement of the bone and may tend to increase destruction by disturbance of the blood supply.

Wilensky⁶ has shown that foci of hematogenous osteomyelitis may subside completely and spontaneously without going on to the stage of necrosis and sequestration; that similarly sequestered areas of bone can and do become revascularized and reincorporated with neighboring bone tissue in much the same manner as a bone graft. He likewise has expressed the belief that acute hematogenous osteomyelitis is an incident in a general bacterial infection:

In the treatment of this disease in the early stages the most important item is the general infection. The ultimate outcome, death or recovery, depends entirely on this factor, and the mortality statistics of acute hematogenous osteomyelitis in its early stages reflect accurately the mortality of general bacterial infection. When divorced from the general bacterial infection and in the absence of any fatal complications or associated lesion, the mortality of the local osseous lesion is nil.

Since the advent of sulfathiazole the literature has been voluminous in reports of both the experimental and the clinical uses of the drug. Barlow and Homburger¹² have shown that sulfathiazole has definite bacteriostatic and bactericidal effects on the staphylococcus, both in vivo and in vitro. They have demonstrated also that the life of experimental mice infected with highly virulent strains of *Staphylococcus aureus* is prolonged and that abscesses in the kidneys and other organs are prevented or healed by the use of sulfathiazole.

Repeated reports have established the fact that sulfathiazole definitely sterilizes the blood in staphylococcic septicemia, effecting a cure.¹³ Local lesions caused by the staphylococcus have also shown favorable results from internal administration of the drug.

Sulfathiazole is being used generally in the treatment of both acute and chronic osteomyelitis, but to date few reports have appeared. Dickson and his associates¹⁴ have used it both internally and locally in a series of cases of chronic osteomyelitis, with favorable results. Melton¹⁵ reported 10 cases of acute osteomyelitis in which it was used internally but in association with incision and drainage. He stated that it did not lessen the need for surgical drainage or check the progress of suppuration. It did lessen toxemia.

To date there have been no published reports of internal treatment with sulfathiazole without drainage of the local abscess. Nachlas¹⁶ has treated a series of patients

in this manner without any operative procedure and reported excellent results. His work will appear in the literature at an early date. Badgley¹⁷ has treated several patients with sulfathiazole, delayed incision and drainage with good results. He has also treated a secondary bone lesion in 1 of his cases without surgical intervention.

Since August 1940, in 8 consecutive cases of acute osteomyelitis treatment with sulfathiazole without operation has been given at the Children's Hospital. The unusual course of the disease and the abscess, contrary to all previous experience and associated with end results superior to anything that we have heretofore seen, leads us to review the 8 cases.

METHOD OF TREATMENT

The treatment here outlined should be undertaken only in a hospital, under the most competent supervision. On admission supportive treatment is given, and the pain is controlled by immobilization and the administration of mild sedatives. Oral sulfathiazole therapy is instituted immediately. The initial dose is determined by the body weight of the patient. A safe dose for

It is advisable to give transfusions of 300 to 500 cc. of whole blood every few days during the first two weeks and at less frequent intervals thereafter, depending on the condition of the patient.

The treatment of the local lesion is that of nonintervention. Wet packs have been employed, but they are of questionable value. Immobilization during the painful stage of the abscess is advised and is best carried out by posterior splinting or extension. The duration must be determined by the condition in the individual case. Obviously, for extremities with extensive involvement of bone and danger of spontaneous fracture, immobilization must be employed over a longer period of time. As a rule, however, after the abscess begins to recede, rigid immobilization should be discontinued and passive and active motion of the part should be started. This results in less atrophy and better repair. The local lesion is protected against trauma by thick dressings, as spontaneous rupture of the abscess is to be avoided.

Care after discharge from the hospital is likewise dependent on the condition in the individual case. The same methods of protection as are employed in any

TABLE 1.—Summary of Cases

8. J. B.	10	♂	February 1941	Furunculosis	Staph. aureus	Metatarsal, great toe	—	+	33	Normal function; no drainage

initial administration is 1 to 1½ grains (0.06 to 0.1 Gm.) per pound (0.5 Kg.) per day. For a child of 100 pounds (45.4 Kg.) the initial dose would be 20 grains (1.2 Gm.) every four hours. Subsequent dosage is regulated by determination of the blood level of the drug. An attempt is made to maintain the blood level at 4 to 6 mg. per hundred cubic centimeters throughout the treatment. To accomplish this, one must give the drug every four hours because of rapid excretion. An equal dose of sodium bicarbonate is given simultaneously.

Since on admission patients with acute osteomyelitis are dehydrated, liquids are immediately forced and saline solution is given intravenously. The procedure is repeated as often as necessary to maintain a normal relation of intake and output of fluids. While the forcing of liquids may lower the blood level of the drug, it is better to increase the dose than to decrease the intake of fluids. Renal complications if present are the result of crystalline deposits in the tubules of the kidney, and concentration and acidity of the urine are to be avoided. Administration of sulfathiazole is continued unless contraindicated for at least two to five weeks at full dosage. The duration of therapy is determined by the condition of the patient and the course of the disease.

other type of treatment should be used, but the problem is simplified because there is no draining sinus. Weight bearing with protection is instituted as early as the local lesion will safely permit it.

REVIEW OF CASES

Table 1 gives a summary of the data in the 8 cases reported. In 6 there was a history of some previous cutaneous infection, the most common lesion being furunculosis (4 cases). The staphylococcus organism

Fig. 1 (case 7).—Osteomyelitis of shaft of ulna.

was demonstrated in 7 cases either by blood culture or by aspiration of the local abscess. In case 3 no organism was demonstrated.

Repeated blood cultures were studied in all the cases. In 5 of these, cultures of material obtained at some time during the first week and a half were positive. After this period no positive reports were returned, although

17. Badgley, C. E.: Personal communication to the authors.

blood for culture was taken every few days during the hospital stay. The colony count varied from ninety per field (case 1) to three to four (case 8).

The local abscess was aspirated early for diagnosis in 5 cases, and culture of the aspirated material was reported positive. In 3 of these cases aspiration was

drain seropurulent fluid from which *Staph. aureus* could be cultured. This drainage persists, although it appears superficial and does not seem to lead to bone.

The symptoms in this series at onset were similar to the symptoms in any other group of cases of acute staphylococcal osteomyelitis. There were severe toxemia, a high temperature and swelling and pain in the extremities. In case 1 the most severe systemic reaction in the whole series occurred. There was a positive blood culture of ninety colonies per field, and the osteomyelitis was complicated with a chest condition producing material from which *Staphylococcus albus* could be cultured. The patient was treated in an oxygen tent for ten days and had the severest soft tissue involvement of the shoulder, neck and face that we have ever encountered. Any type of operative treatment was contraindicated. Considered moribund, the patient was treated symptomatically and given sulfathiazole. In the third week of treatment two small exploratory incisions were made in the skin over the scapula. No pus was encountered, and the incisions were closed with sutures. Primary healing took place, and cultures of material from this area were sterile. The favorable end result of treatment in spite of the general condition, the roentgen appearance and the local soft tissue lesions led us to treat subsequent patients with sulfathiazole without operation. Many of the other patients presented severe general and local symptoms and responded equally well.

The majority of patients showed little improvement until the second week. The temperature remained ele-

Fig 2 (case 1) —Appearance ten months after onset of osteomyelitis

repeated three to five weeks later, and the cultures were negative. The late aspirations were made after rather long administration of sulfathiazole.

Leukocytosis, the white cell count varying from 40,000 to 15,000, was present in all the cases during the early stage of the disease. In several cases there was a fall in the red blood cell count and the hemoglobin content during the second week. The urine remained normal in the whole series throughout the hospital stay. Frequent determinations of the blood sulfathiazole level were made. The highest level in any case was 14 mg. per hundred cubic centimeters (case 6). In case 3 2.8 mg. was the highest level that could be maintained. The average for the series was 4 to 6 mg. per hundred cubic centimeters during active administration of sulfathiazole.

For the first two weeks the local soft tissue lesions presented the same appearance as any other acute inflammatory abscess. Then they became less hot and tense and smaller and were less painful. In three to four weeks the inflammatory area if still present became darker and did not feel hot, and an indurated border and a soft, rubbery center developed. As time progressed, the local lesion completely disappeared and the skin took on its normal appearance.

In case 7, in which a most extensive involvement of the ulna and the forearm occurred, the local lesion remained closed for four months. There persisted over the forearm three discolored areas with soft centers. After being struck with a toy these lesions started to

Fig 3 (case 6) —Osteomyelitis of right side of ilium. appearance five months after onset.

vated for two to six weeks and in several cases was higher in the second and third weeks than in the first. Even though the temperature remained elevated this late and the local lesion was still present, the general condition and the toxemia were much improved. The patients were bright and alert and required no medication for the local lesions.

Roentgen studies made at onset in all cases followed by frequent rechecks up to the present have shown extensive bone changes. The primary bone lesion has progressed at first much as it does in similar cases in which treatment is by incision and drainage without sulfathiazole. Areas of absorption have been followed by bone proliferation and in 3 cases by definite sequestration (cases 5, 7 and 8). As time has passed the areas of sequestration in cases 5 and 7 have disappeared and have become incorporated into the substance of the ulna and of the fibula respectively.

Fig. 4 (case 6) —
End result.

In case 7 the whole shaft of the ulna was involved (fig. 1). Two months later an unusual amount of proliferation appeared, increasing the diameter of the bone. This at first cast a faint shadow but later became more calcified and gave the appearance of an involucrum. At the end of six months a decrease in the size of the bone occurred, with reestablishment of a more normal contour. In case 1 enormous bone proliferation involved the whole bone (fig. 2), and this has persisted, although it has taken on more nearly the appearance of normal bone. In case 4 there was little bone proliferation in the clavicle, and studies of the end results reveal a well healed lesion. In case 6 the disease of the humerus has progressed like any other osteomyelitis (figs. 3 and 4) except that the involvement is not as

extensive as that usually found. In case 3 the disease was confined to the upper end of the tibia and after eight months has almost completely disappeared.

In cases in which more than one bone was involved little bone proliferation is observed in the secondary lesion, and after six to eight months the lesions are well healed. In case 2 there was a secondary lesion of the epiphysis of the femur and of the patella, but healing appears to have taken place.

End results are considered from the standpoint of the general condition and the local lesions. The excellent physical condition of the patients is impressive. Asymptomatic after two to three months, they have the appearance of normal, healthy children, have gained weight and have normal blood counts. Short hospitalization and immobilization, with early return to normal activity without plaster casts or draining sinuses, have produced none of the usual appearances of the septic, anxious patient who has been operated on for osteomyelitis.

The end results of treatment of the local lesion have been most satisfactory to date. In only 2 cases has any drainage developed. In case 1, eight months after onset a serous drainage developed in the site of the incision in the skin over the scapula. This was superficial and persisted for only two weeks. Culture of material obtained from this area was not positive. In case 7 the lesion is still draining after a direct trauma to the region of the ulna, and culture shows *Staph. aureus*. In 6 of the 8 cases there has been an increase in size of the part affected. This is evident both to inspection and by measurement but is becoming less apparent as time goes on. Only 2 patients have shown

any limitation in function. Patient 1 (fig. 2) has limitation in rotation of the shoulder of about 50 per cent. Abduction of the shoulder is limited to 45 degrees. There is also definite muscular weakness of the shoulder girdle. Patient 7 at this time has almost complete limitation in pronation and supination of the forearm, and flexion and extension of the elbow and the wrist are diminished about 50 per cent. Patient 6 has slight tilting of the pelvis. The progress of the osteomyelitis, data on sulfathiazole therapy and the end result in case 5 are shown in figures 5, 6, 7 and 8.

Practically no atrophy has resulted in the region of the local lesion, and the color and the character of the skin have returned to normal. There appears to be no evidence of induration except in patient 7, whose lesion is draining.

Of the 8 patients treated, only 1 remains in the hospital at this time. The longest hospital stay has been one hundred and twenty days and the shortest twenty-one days, with an average of fifty-four days for the series. With increasing experience in the treatment of the disease we believe that the hospital stay can be considerably reduced. Seven patients have returned to school. Two are using crutches for protection, 1 of whom has a light foot cast to prevent weight bearing.

COMPLICATIONS

Children tolerate sulfathiazole well. Fortunately acute osteomyelitis occurs mostly in children and young adults. To date we have had no complication which has made it impossible to carry out the required treat-

Fig. 5 (case 5) —Progress of osteomyelitis. A, seven days. B, two to three days after onset.

ment. In 2 cases a cutaneous eruption appeared simulating erythema nodosum. In 1 of these the drug was withdrawn for two days, the condition cleared up and use of the drug was resumed. In the other the drug was not withdrawn and in three days the cutaneous

condition disappeared. There were no renal complications. Accurate studies of the intake and output of fluid were made, and the amounts remained well within normal range in all cases. In case 7 after prolonged use of the drug over several weeks conjunctivitis developed, necessitating discontinuance. In several cases some nausea was encountered during the first few days but never was a serious problem. In 2 cases we found that the temperature remained elevated until administration of the drug was discontinued. This may be true oftener than is realized. We do not hesitate to discontinue administration of the drug at any time when in doubt as to a complication. Few serious complications of the drug's use have been reported. Long

Fig. 6 (case 5).—Further progress: A, six weeks, B, six months after onset.

and his associates¹⁸ have described in detail the complications produced by sulfathiazole and its toxicity as compared with that of sulfapyridine and sulfanilamide.

COMMENT

Osteomyelitis is primarily a bacteremia, and the bone lesion is secondary. Nussbaum¹⁹ showed that the terminal arteries at the metaphysis are dilated, forming a so-called venous lake. Here stasis can occur and bacterial masses as large as 20 microns can lodge. With the slowing of the blood stream, lessened phagocytosis occurs and favorable conditions for an inflammatory process arise. This extends to the periosteum and later, after a certain amount of elevation, breaks through into the soft tissue. If undisturbed surgically the abscess ruptures spontaneously, creating a sinus directly

to the bone. When incision and drainage are done, either early or late, the same situation is artificially produced. When operation is used in a case of acute osteomyelitis it follows that there must be some disturbance in the blood supply to the bone and the soft

Fig. 7 (case 5).—Clinical course in hospital.

tissues as a result of the operation. Also, when continued drainage or packing is employed in the after-treatment there is sure to be a mixed infection involving the whole inflammatory area. It is difficult to evaluate

Fig. 8 (case 5).—End result

how much these two factors have affected the acute and chronic course of the disease in the past.

It has been shown that when sulfathiazole is administered there is a definite blood concentration which can be maintained at a desired level. It has also been shown that material aspirated from an abscess of acute

18 Long, P. H.; Haviland, J. W.; Edwards, L. B., and Bliss, E. A.: The Toxic Manifestations of Sulfanilamide and Its Derivatives, J. A. M. A. 116: 364 (Aug. 3) 1940.
19 Nussbaum, A.: Beziehungen der Knochengefäße zur akuten Osteomyelitis, Zentrabl. f. Chir. 49: 700, 1922

osteomyelitis treated by sulfathiazole will show a concentration as high as if not higher than that of the blood taken at the same time. We think it can be assumed from these observations that there is a diffusion of sulfathiazole into the whole inflammatory area as well as into the blood. The maintenance of a sulfathiazole concentration in both the blood and the inflammatory area would attack the staphylococcus organism wherever it might be.

It is our opinion that in cases of acute osteomyelitis sulfathiazole can eventually sterilize both the blood and the local lesion. We have shown on several occasions that culture of material aspirated early is positive for the staphylococcus and that culture of material aspirated late is negative. As further evidence, there came under our observation a case not included in this series in which incision and drainage of an abscess over the scapula was made after four weeks of sulfathiazole medication. No pus was found, but a yellow serous fluid was present. There was evidence of a healing process, a copious blood supply and excessive granulation tissue. Cultures of material from this abscess were negative.

It appears that in our series the earlier administration of the drug was started after the first symptom was recognized the shorter was the period of elevation of the temperature and the less the involvement of bone

not be drawn, but there are evident improvements over previous end results. Only ten months have elapsed since the onset of acute osteomyelitis in the first patient treated, and what the ultimate result will be after one, two or ten years cannot be predicted. Comparison of these patients with any other series of patients, however, shows striking differences. There has been no mortality; hospitalization and disability have been shorter; there have been no draining sinuses except late in 1 case; no operations have been performed, either primarily or secondarily; deformities and limitation in motion have been minimal. The patients are not invalids and with the exception of 1 still under treatment are carrying on normal activity and attending school.

The most revolutionary part of the treatment suggested in this paper is the handling of the local lesion without operation. Surgeons trained under the precept and surgical principle "Where there is pus, drain" find it extremely difficult to refrain from surgical intervention. However, by waiting we have repeatedly seen painful, red, hot, fluctuating abscesses, from which pus which produced positive cultures could be aspirated, change into painless, pale, soft, doughy areas which yield negative cultures and finally completely disappear.

The second week is the most difficult time to pass without resorting to surgical procedures. The use of sulfa-

TABLE 2.—Data on Sulfathiazole Therapy

Patient	Age	Sex	Lesion	Onset of Symptoms	Beginning of Therapy	Daily Dose	Days of Treatment	Blood Level, Mg. per 100 Cc.	Appearance of Normal Temperature
1	11	♂	Scapula, humerus	8/17/40	5th day	6 Gm.	45	2.5 to 7	42d day
2	11	♂	Femur, tibia	7/10/40	3d day	6 Gm.	14	5.5 to 5.8	14th day
3	6	♂	Tibia	9/17/40	13th day	6 Gm.	41	4.4 to 5.7	14th day
4	14½	♂	Clavicle, femur	9/28/40	3d day	4 to 10 Gm.	37	3.3 to 8.3	30th day

8	10	♂	Metatarsal	2/15/41	10th day	3 Gm.	34	2.3 to 9	13th day

(table 2). We have observed in the last ten months 3 patients with positive blood cultures who had tenderness and pain over the long bones. They were given sulfathiazole within two or three days after the onset of symptoms. No local abscess occurred, and there was no roentgen evidence of involvement of bone. Obviously these were not included in our series, but we feel it is possible that these 3 patients had acute osteomyelitis which because of the early administration of the drug did not follow the usual course.

From the study of the roentgenograms in this series it does not appear that the extent of the involvement of bone has been lessened. On the contrary, the typical degenerative changes of acute osteomyelitis have been followed by sequestration and the formation of an involucrum with ultimate excessive bone proliferation. As time has elapsed this proliferation has decreased, much as does a callus about a fracture. Regardless of how soon the temperature returned to normal or how soon the drug was given after the onset of the disease, these bone changes have occurred. We agree with Long,²⁰ Wilensky and other investigators that the sequestrums if sterile become revascularized and act as a bone graft.

The disadvantages of previous methods of treatment for acute osteomyelitis have been a high mortality, long hospitalization, persistent drainage, multiple secondary operations, deformities and invalidism.

Our series of patients treated by sulfathiazole without operation is not large, and too many conclusions should

thiazole produces no immediate, spectacular results. The bacteremia and toxemia of the patient will improve rapidly, but the elevation of temperature will continue, and there may be at first an apparent increase in the abscess. Continued elevation of the temperature and an increase in the abscess during the second week are not an indication for surgical procedures, however.

We object to incision and drainage with the use of sulfathiazole because the blood supply to the bone and the surrounding tissue is disturbed, interfering with the diffusion of the drug. With a draining sinus it is impossible to maintain a high concentration of sulfathiazole. Operation inevitably is followed by secondary infection through the draining sinus, producing the same set of conditions so objectionable in the older methods of treatment. The goal of this treatment of staphylococcal osteomyelitis by sulfathiazole without operation is the sterilization of both the blood and the local lesion. If that can be accomplished the bacteremia and toxemia will be controlled and repair in the bone and soft tissue will proceed normally.

CONCLUSIONS

1. In 8 cases of acute staphylococcal osteomyelitis in which treatment with sulfathiazole without operation has been given the end results after 10 months appear to be better than results obtainable by other methods.
2. The bacteremia, as evidenced by positive blood cultures, was controlled by the administration of sulfathiazole without incision and drainage of the local abscess.

²⁰ LONG, P. H.: Personal communication to the authors.

3. Abscesses have occurred of which cultures at first were positive for staphylococci but after sulfathiazole administration were negative.

4. Acute fluctuating staphylococcal abscesses have completely disappeared without incision and drainage.

5. Sulfathiazole does not appear to decrease the involvement of bone in primary lesions. In some cases there has been an increased proliferation.

6. Secondary bone lesions show fewer changes and return more quickly to normal appearance.

7. Sequestration may occur and when it does appears to act as a sterile bone graft.

8. There were no deaths in the series.

9. Treatment by this method must be instituted in a much larger series of cases and a longer period must elapse before final evaluation of its merits can be ascertained.

AUTHORS' NOTE.—Since the presentation of these eight cases in June, additional patients have been treated without operation with similar results. These include two cases of septic arthritis of the hip with bone changes. There have been no recurrences in any of the cases, and seventeen months has elapsed since the first case was treated.

407 Ohio Building.

ABSTRACT OF DISCUSSION

DR. CLARENCE H. HEYMAN, Cleveland: I have had no experience with this method of treatment as described by Drs. Hoyt and his collaborators. This is further evidence of the trend toward conservative treatment of acute osteomyelitis. It is difficult to keep hands off when we have been brought up on the axiom that where there is pus surgical drainage is required. Even with simple bone drilling it has been my experience that the progress of the disease and bone destruction with sequestration continue. Dr. Greene of the Children's Hospital of Boston not long ago gave us courage to delay any sort of operative treatment in very young children until the formation of a localized abscess. However, we recognize that in infants the infecting organism as a rule is the streptococcus rather than the staphylococcus. The authors now go still further in keeping hands off, but with the addition of sulfathiazole. They are to be congratulated on their courage. After studying the material in their exhibit I have been sufficiently impressed to adopt this method at least for a trial.

DR. CARL E. BADGLEY, Ann Arbor, Mich.: In February I showed Dr. Hoyt a case of osteomyelitis of the ilium associated with a pyarthrosis of the hip, which was treated by our usual procedure with incision and drainage of the involved area, with drainage of the abscess of the iliac fossa and drainage of the pyarthrosis, followed by sulfathiazole, with the wound kept open by petrolatum gauze. There was a prompt dropping of temperature. The child convalesced rapidly, so that an early secondary closure with sulfathiazole in the wound was followed by healing of the wound and with excellent range of motion in the hip joint. This child has an excellent hip. He has no drainage. The wound has healed and is doing very well. This has been our standard method of treatment for acute hematogenous osteomyelitis. The authors have presented something that should not be considered as a proved method of treatment but something that should be utilized from an experimental point of view. We should have an open mind and if possible see if this is not a good method of treatment. I feel convinced, as Dr. Key does, that the open operation plus the local implantation of sulfathiazole is a good procedure. Can we get away from that procedure? Can we, by this oral administration, have these patients get along without the unsightly scars? I don't think that Dr. Hoyt and his co-workers have proved that yet. They have proved that the 8 cases in which they operated did. The cases we have presented have done quite well, but that is not proof that patients can be treated for acute osteomyelitis by this method successfully in large numbers.

DR. LENOX D. BAKER, Durham, N. C.: In certain strains of staphylococcus, one or more of the sulfonamide drugs may be

specific. Recently Miss Mary Poston of our bacteriology department ran *in vitro* determinations on the effectiveness of the sulfonamides on fifty-seven strains of staphylococcus. The studies were made on broth cultures with various concentrations of the drugs up to 10 mg. I am aware that *in vitro* studies will not tell us all we want to know, but they do help in determining the susceptibility of the organism. Of the fifty-seven strains, twenty-eight were not affected by any of the drugs; twenty-nine were affected by one or more of the drugs, but only eight of the twenty-nine were affected by what we took as a maintainable blood level of sulfathiazole for an average person, that is, 5 mg. per hundred cubic centimeters. Of the eight strains affected by sulfathiazole, four were affected also by one or more of the other sulfonamides. Seven of the 8 cases which Drs. Hoyt, Davis and Van Buren have presented came from the same locality and their infections occurred between August 1940 and February 1941. Of the 7, 6 had some kind of cutaneous lesion. Could these patients have had a common infection of staphylococcus which was susceptible to sulfathiazole? If so, naturally one would expect the results which have been shown. My associates and I have treated 15 cases of staphylococcal septicemia with sulfathiazole. In some of the cases the results have been most satisfactory but evidently not all strains of this organism are affected by the sulfonamides. As to incision and drainage interfering with the blood supply, the thing that makes the staphylococcus such a potent organism is its toxin, which has four major actions: it coagulates plasma, it necrotizes tissue, it destroys young leukocytes and it hemolyzes red cells. We all have had the same experience in operating on acute osteomyelitis. As we make our incision there are a few skin bleeders, but the remainder of the tissues have no real capillary bleeding, as the plasma is coagulated. Dr. Key states that when he makes sulfathiazole determinations on the pus it usually runs somewhere less than 50 per cent of what the concentration is in the blood, so like Dr. Key I feel that it is a good idea to drain the abscess and put the sulfathiazole in the wound.

DR. FREDERICK A. JOSTES, St. Louis: Dr. Alexis F. Hartman, professor of pediatrics at Washington University School of Medicine and chief at St. Louis Children's Hospital, has treated acute osteomyelitis with chemotherapy for a period of two years. It was my privilege to see most of these cases through the entire process. I have also treated some adults. It is my belief that the results obtained by judicious administration of the sulfonamide drugs locally and by mouth with early incision, when aspiration fails to define the organism causing the infection, are as good both roentgenologically and in the course of the illness as they are in those cases in which incision is not made and that these cases afford less hazard to the patient and worry to the doctor. We have a rather large proportion of cases in which *Streptococcus hemolyticus* and not the staphylococcus was the cause. Local application of the necessary drug was made after incision as well as other forms of administration to keep up the blood concentration sufficiently long not only to stop the spread of infection but to prevent recurrences, which are so frequently seen because the drug in small doses was not given over a sufficiently long period of time after the temperature and symptoms subsided. At no time were bones drilled or was the cortex broken surgically. Our x-ray results are not very different from those of Dr. Hoyt and his co-workers. Sclerosing was noted in most of the cases. In my own cases I incised early—early meaning when we got the cases within thirty-six or forty-eight hours—the drug was put into the area as well as given by mouth. We irrigated many of the old abscesses, and in many cases even though the temperature had been normal for some time the abscess was not sterile until after irrigation with the drug solution.

DR. WALTER A. HOYT, Akron, Ohio: We were impressed with the pathologic condition in 1 case which was seen simultaneously with the first case treated. This case, one of osteomyelitis of the scapula, had been treated by sulfathiazole without operation for four weeks before admission. The patient was afebrile and asymptomatic and examination showed a dough-like swelling over the scapula. Incision and drainage were done but pus was not encountered. There was present a serosanguineous fluid, and it had the appearance of granulation tissue with a copious blood supply. Culture from this area was negative. We have encountered many men this week in our exhibit who have been

working with sulfathiazole. We have had a good cross section of what is going on over the country in this work. It has been interesting to hear a description of the pathologic condition found when operation has been performed late in the disease. Dr. Nachlas of Baltimore has treated quite a series of cases in the manner we have suggested without operation. Dr. Perrin Long feels that we are justified in continuing with this type of treatment. It is going to take men like Dr. Baker and a great deal of investigative work to stabilize the method that is to be followed as far as osteomyelitis is concerned. Dr. Key said he knew a patient who had died after sulfathiazole treatment. I have seen many patients die after operation, and I believe that many of them have died because they were operated on too early. The most convincing part of the whole treatment is the appearance of the patients. They are healthy and have returned to school and normal activity. They have no draining sinus, no atrophy, no loss in range of motion, no pain and no "smell." We are going to continue conservatively. We want to see what these cases are going to do after one year, two years, three years and longer after onset. We do not expect 100 per cent results. We expect that in some of these cases drainage will occur. We are going to report on these cases later. If any physicians treat any cases of osteomyelitis in the manner described by us, we would appreciate hearing from them. Dr. Van Buren, our surgical resident at Children's Hospital, is responsible largely for starting this work, and Dr. Roberts and the other members of the staff made it possible for us to carry it on.

SPONTANEOUS PNEUMOMEDIASTINUM IN THE NEWBORN

BERNARD GUMBINER, M.D.

AND

MEYER M. CUTLER, M.D.

CHICAGO

It has been stated that more than one third of all deaths of infants occur during the first two weeks of life.¹ Asphyxia and atelectasis are listed second only to prematurity as the cause of death in the neonatal period.¹ Few symptoms are the source of more concern to the pediatrician than dyspnea and cyanosis in the newborn infant. In many instances, although definite abnormal physical signs in the heart and lungs are not elicited, a diagnosis of congenital atelectasis is made. In some cases the symptoms become progressive and lead to death despite therapeutic measures such as clearing of the air passages, administration of oxygen, stimulation and blood transfusions. Many physicians when confronted with dyspnea and cyanosis in the newborn have had a feeling of inadequacy from the aspect both of accurate diagnosis and of adequate treatment.

This sense of inadequacy can be relieved in part by recognizing spontaneous pneumomediastinum as a possible cause of these alarming symptoms, by diagnosing it when it is present and by instituting appropriate treatment. It is hoped that the description of the diagnostic and therapeutic procedures will serve to prevent some of the tragic deaths in the neonatal period.

Cases of pneumomediastinum or mediastinal emphysema in the newborn have been described before, but the

reports have been few and their real import not recognized. In 1928 Stransky² reviewed the literature of pneumomediastinum and discovered that as early as 1853 Guillot³ had reported 2 cases of the condition in the newborn, the diagnosis in both having been made at autopsy. We have been able to find reports of only 8 additional cases since that time: 2 cases reported by Schuler⁴ and 1 each by Kirchgessner,⁵ Faber,⁶ Rosenblum,⁷ Poeck,⁸ DeCosta⁹ and Fisher.¹⁰

No mention of the syndrome is made in general pediatric textbooks or treatises on the newborn in common use. Failure to recognize the condition would seem to be due to the fact that an adequate clinical description of the syndrome and a recognition of its importance have been lacking. Recent animal experimentation by C. C. Macklin¹¹ and by Fisher and Macklin¹² and a description of the syndrome in adults by Hamman¹³ have served to bring the subject to the attention of the medical profession once again. None of the reports which we have found have stressed sufficiently the pathognomonic appearance of the lateral roentgenogram,¹¹ and as far as we could determine no one has ever employed simple therapeutic aspiration.¹⁵ It is these measures, essential for diagnosis and therapy, that we wish to stress most in our presentation.

In March 1940 we observed our first case of mediastinal emphysema in the newborn infant, and it was the dramatic result obtained in this instance that prompted us to look for more cases and to present this report.

The patient was a boy weighing 9 pounds (4.1 Kg.), born by normal delivery at the Michael Reese Hospital. He required no resuscitation at birth, his cry was good and there was no dyspnea or cyanosis. About thirty hours after birth he suddenly became dyspneic and cyanotic. Examination disclosed the following essential features: Severe cyanosis was present, with distention of the veins of the neck. The respiratory rate was more than 130 per minute. The heart tones were distant, and no murmurs could be heard. No abnormal breath sounds could be made out, although there was some suppression of sounds over the posterior portion of the chest. There was no subcutaneous emphysema and no bulging of the precordium.

The infant was placed in a Hess oxygen bed, and stimulants were administered. An emergency roentgenogram showed, in the posterior-anterior view (fig. 1), distortion of the cardiac

From the Pediatric and Roentgenologic departments of Michael Reese Hospital.

Read before the Section on Pediatrics at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

Dr. Gumbiner is associate attending physician of the Children's Division, Cook County Hospital, and formerly was resident physician of the Sarah Morris Hospital; Dr. Cutler is resident roentgenologist, Michael Reese Hospital.

The following physicians gave permission to include in this report cases from their private and ward services at Michael Reese Hospital: Drs. Philip Rosenblum, Arthur Abt, Carl Cohen and Emanuel Padnos. Dr. Henry G. Poncher permitted inclusion of the case from the tuberculous service of the Cook County Hospital.

Holt, L. E., and McIntosh, Russell: Holt's Diseases of Infancy and Childhood, ed. 11, New York, D. Appleton-Century Company, Inc., p. 56.

contour, with apparent displacement of the upper part of the heart shadow and of the mediastinal structures to the right. There was an area of radiolucency just to the left of the mediastinum in the region of the second to third intercostal spaces, and there was some increased density in the upper part

Fig. 1 (case 1).—Posterior-anterior view of the chest showing bilateral radiolucent shadows just lateral to the margins of the superior mediastinal density. These represent pools of air in the anterior mediastinal space. The cardiac shadow is suggestively abnormal in size and configuration. The heart and the superior mediastinal structures are partially displaced to the right. The upper areas of the lung fields have the appearance of either pulmonary congestion or patchy atelectasis, while the lower areas of the lung fields are hyperaerated.

of the right lung field. A lateral view (fig. 2) taken at the same time showed a distinct area of radiolucency beneath the sternum apparently displacing the heart and the mediastinal structures posteriorly. Study of the second film established the diagnosis of pneumomediastinum. During the succeeding twenty-four hours the condition of the infant became progressively worse, and a new roentgenogram showed some increase in the amount of mediastinal air. At this time the infant's

Fig. 2 (case 1).—Lateral view demonstrating sharply delineated shadows of encapsulated air in the anterior mediastinum just behind the posterior surface of the manubrium and the body of the sternum. Another globule of air is present in the region of the suprasternal notch. The shadows of the heart and the superior mediastinal structure are crowded and displaced posteriorly because of increased mediastinal pressure. Note the striking appearance in this view as compared with the posterior-anterior view (fig. 1).

condition seemed critical, and after consultation it was decided to attempt aspiration of the air.

A 21 gage needle attached to a 20 cc. Luer syringe was inserted into the third left interspace 1 cm. to the left of the sternal border and directed medially, parallel to the inferior

surface of the sternum. There was a sudden expulsion of the plunger of the syringe to the 6 cc. mark, indicating the release of air under pressure. Within five minutes there was a dramatic change in the baby's condition. The color became pink, the respiratory rate dropped to about 100 per minute and the infant started to cry and to move about in his bed. A roentgenogram taken ten minutes after aspiration (fig. 3) showed that approximately 70 per cent of the air had been removed. Within three days the infant was clinically well, and roentgenograms showed complete disappearance of air.

The diagnosis in this case was made because lateral roentgen examination was done. As this procedure is not commonly carried out in the examination of the newborn it was felt that we might have been missing the diagnosis in a certain percentage of cases. Proof that we had been doing so was obtained when 3 additional cases were discovered during the next four months. In 2 of these the symptom was slight dyspnea. Enlargement of the thymus gland was suspected. The diagnosis of pneumomediastinum in both instances was obvious from lateral roentgenograms. In the third case there were moderate dyspnea and cyanosis, with some bulging of the precordium, absence of cardiac dullness and distant heart tones. The clinical impression of pneumomediastinum was substantiated by roentgenograms (figs. 4 and 5). Successive roentgenograms in this case were of great interest, as they showed an increasing mediastinal accumulation of air and finally spontaneous pneumothorax coincident with clinical improvement and evidence of reduction in mediastinal emphysema.

Fig. 3.—Lateral projection made immediately after therapeutic substernal aspiration. The air in the anterior mediastinum is now considerably diminished. Dramatic clinical improvement occurred within five minutes after aspiration.

It is interesting to speculate on the possibility that spontaneous pneumomediastinum may play a part in the production of types of spontaneous pneumothorax. One of us (B. G.) recently had an opportunity to observe a patient in the service of Dr. Henry G. Poncher, at the Cook County Hospital, Chicago, a 6 month old infant who had tuberculosis, in whom there developed pneumomediastinum and, subsequent to an increase in the amount of mediastinal air, spontaneous pneumothorax.

Davis and Stevens¹⁶ reported that in 6 of 702 consecutive newborn infants the presence of spontaneous pneumothorax was proved by roentgenograms, an incidence of approximately 1 per cent. If pneumomediastinum was the precursor of pneumothorax in most instances one might expect an incidence of mediastinal emphysema of more than 1 per cent. as obviously pneumomediastinum does not lead to pneumothorax in all cases.

MECHANISM OF PRODUCTION

Spontaneous pneumomediastinum has been shown to result from pulmonary alveolar rupture (fig. 6) with subsequent passage of air through the interstitial tissue of the lung to the mediastinum. Macklin's¹¹ experimental work, done chiefly on cats, has demonstrated this mechanism conclusively. He showed that, when overdistention of a portion of the lung was artificially induced, alveolar rupture occurred, with the passage of air along the vascular sheaths to the mediastinum. It follows, therefore, that any condition which would tend to produce overdistention of a portion of the lung might result in mediastinal emphysema. The delicacy of structure of the lung of the newborn infant, and especially that of the premature infant, would seem to be a definite predisposing cause.

PATHOLOGIC CHANGES

Clinical and experimental work has shown that air in the mediastinum may extent upward to produce subcutaneous emphysema of the neck, may extent downward through the aortic hiatus to the retroperitoneal space and then, by rupture of the peritoneum produce pneumoperitoneum; or may rupture through the mediastinal pleura to produce pneumothorax (fig. 7). DeCosta⁹ reported a case in which mediastinal emphysema, subcutaneous emphysema, pneumoperitoneum and pneumothorax all were present. In addition, a patient may have subcutaneous emphysema of the chest and the abdominal wall, interstitial emphysema of the uninvolved portions of the lung, pneumoprecordium or subcu-

taneous emphysema of the groin and thigh.

If the air remains in the mediastinum and is under tension, various changes due to pressure on the surrounding structures may occur. The heart, great vessels, trachea, bronchi, lungs and vagosympathetic plexus all may be affected. Jehn and Nissen¹⁷ have shown that no symptoms are evident until the intramediastinal pressure reaches zero. They found that as the pressure increases on the positive side changes occur rapidly and proceed as follows:

At first respirations become increased and shallow. Soon there is a

Fig. 4 (case 4).—Posterior anterior projection. There is partial pneumothorax on the left side. Note the bilateral lateral to the margins of the mediastinal air.

drop in blood pressure. The pulmonary and systemic veins are the first affected, because of their elastic, easily compressed walls. By compression of the

systemic veins the return flow of blood to the right auricle is diminished, and at the same time compression of the pulmonary veins causes diminution of the flow into the left auricle. There thus results congestion of the peripheral veins and of the lungs. The latter is an early sign and explains the dyspnea. The

Fig. 5 (case 4).—Lateral projection. There is encapsulated air in the anterior mediastinum subternally, and pneumomediastinum is present. Note the striking appearance as compared with the posterior anterior view. Bulging of the precordium is clearly evident.

direct effect of compression on the trachea and bronchi and even the lungs themselves seems to be only a small factor in the production of dyspnea. The air in the mediastinum displaces the heart downward and posteriorly, so that the heart tones are apt to be distant and the percussion note over the heart tympanitic. Air over the heart may give rise to a peculiar crackling sound, synchronous with systolic contraction. This sound has been stressed as being of diagnostic value in the adult.¹⁷

From the foregoing discussion it would seem logical that many of the conditions mentioned might be ameliorated if spontaneous decompression of the mediastinum resulted with the formation of pneumothorax, subcutaneous emphysema or pneumoperitoneum. It also seems obvious that if spontaneous decompression did not occur and symptoms became alarming therapeutic decompression would be indicated.

SIGNS AND SYMPTOMS

Mediastinal emphysema in the newborn usually occurs during the first days of life. The condition manifests itself by respiratory and circulatory distress. Respirations become rapid and shallow, and cyanosis appears. Distention of the peripheral veins occurs, usually seen most easily in the neck. Heart tones are often distant, and one may hear a crackling sound synchronous with the heart beat. Occasionally one may note bulging of the precordium. Percussion fails to elicit cardiac dullness. If spontaneous rupture occurs one may feel subcutaneous emphysema or obtain signs of pneumothorax.

17. Jehn, W., and Nissen, R.: Pathologie und Klinik des Mediastinal-emphysems, Deutsche Ztschr. f. Chir. 206: 221, 1927.

ROENTGEN DATA

Pneumomediastinum in the newborn may be suspected clinically, but the diagnosis is established definitely by roentgen examination.

The posterior-anterior view may reveal globules of air just outside what are usually considered the lateral margins of the superior mediastinum (figs. 1 and 4). The air shadows are extrapleural. If rupture through the mediastinal pleura occurs, pneumothorax becomes evident.

The lateral projection offers the most conclusive evidence and will in most instances prove to be the diagnostic film. In this projection one sees characteristically one or more pools of encapsulated air just beneath the shadow of the sternum. The density and the extent of the air shadow vary with the degree of emphysema (figs. 2, 3 and 5).

As air in the mediastinum gives rise to pressure phenomena, the lung fields may have the appearance of pulmonary congestion (fig. 1).

TREATMENT

The treatment should be conservative in most instances, oxygen and stimulants being administered as indicated. However, increasing dyspnea and cyanosis are an indication for therapeutic aspiration (case 1).

SUMMARY AND CONCLUSIONS

Spontaneous pneumomediastinum is characterized clinically by the sudden appearance of respiratory distress and varying degrees of cyanosis, with or without such signs as distention of the veins of the neck, bulging of the precordium, distant heart tones, obliteration of cardiac dullness, a crackling sound synchronous with the heart beat, subcutaneous emphysema or signs of pneumothorax.

Fig 6.—Theory of alveolar rupture according to Macklin¹¹ The perivascular sheath is composed of the bases of pulmonary alveoli. Distention of the alveoli causes the perivascular sheath to be drawn away from the blood vessel, enlarging the perivascular space. Increasing pressure in the alveoli plus decreasing pressure in the perivascular space sets up a pressure gradient from the alveoli to the perivascular space and leads to rupture of alveolar bases. A similar pressure gradient results if there is a diminished blood flow to the lung, with consequent diminution in the size of the perivascular space. (This probably explains the high incidence of spontaneous pneumothorax among infants with congenital heart disease.)

The diagnosis is established with the aid of roentgenograms of the chest. The pathognomonic appearance of the lateral view is stressed.

Macklin's experimental work suggested that the cause of spontaneous pneumomediastinum is overdis-

tention of the lung and demonstrated the path of air from ruptured alveoli along the vascular sheaths to the mediastinum.

It appears likely from experimental and clinical observation that pneumomediastinum may secondarily cause pneumothorax, pneumoperitoneum or subcutaneous emphysema.

Fig 7.—The dotted area in the lower part of the right lung field represents an area of alveolar rupture. The shaded areas represent air in abnormal situations. Note that air from the mediastinum may enter the uninvolved portion of the lung and produce interstitial emphysema. The remainder of the diagram is self explanatory and shows the direction of the spread of air. Pneumothorax occurs if there is rupture of the mediastinal pleura, and pneumoperitoneum occurs if there is rupture of the peritoneum.

Treatment is usually conservative, but increasing dyspnea and cyanosis are an indication for therapeutic aspiration.

It is felt that pneumomediastinum in the newborn is a definite clinical entity and that its recognition and treatment, as described in the case reported, should result in a decrease in the neonatal mortality.

2501 Devon Avenue.

ABSTRACT OF DISCUSSION

DR. C. C. MACKLIN, London, Canada: In October 1940 I wrote, regarding pulmonic interstitial emphysema and pneumomediastinum, that "prompt appropriate therapy may save many lives, especially in children," and I feel that Dr. Gumbiner's experience supports this prediction. I am gratified at that accurate diagnosis made in these cases, and particularly for the brilliant demonstration by appropriate x-ray studies. Most of all I am grateful for this demonstration of a clinician who is on the lookout for cases of this sort; for without that attitude and scientific curiosity there can be no progress in this field. I feel assured that aberrant air in the interstitial tissue of the lungs and mediastinum, and contiguous parts, constitutes the basis of a definite clinical entity which has gone undiagnosed in most instances. I have spoken of this clinical entity as "air block," because the air presses on the pulmonary arteries and veins and on the heart and great vessels, so impeding the circulation and giving rise to cyanosis and dyspnea. Air block occurs much more frequently than is realized, and it probably occurs at all ages and under a variety of conditions. Intensive research will give it greater prominence as a serious clinical condition and as a cause of death. Often, I feel, it is associated with bronchopneumonia, and thus its manifestations may be masked. The authors have rendered a real service to the public and medical profession in making known the results of their careful studies. It is a field in which but little work has been done heretofore. That these newborn pneumonopathy cases may end fatally is shown by the experience of John H. Fisher, who has had two cases come to autopsy, one of which has been reported (*Canad. M. A. J.* 44:27 [Jan] 1941). In

this the pathologic findings are like those of the experimental animals which I have studied. I feel that atelectasis is an important predisposing cause, since it is associated with a compensatory emphysema. It is through the weakened bases of the alveoli which overlie the smaller branches of the pulmonary arteries and veins that the air breaks through into the connective tissue around these vessels, and, continuing to leak into these sheaths, it makes its way along them to the mediastinum. As the air accumulates it presses on the vascular system, so impeding the circulation and possibly giving rise to pain as well. In these infants it seems reasonable to assume that there was failure of expansion in certain areas of the lung, with compensatory alveolar ectasia, and that air broke through these stretched alveolar bases, probably during fits of crying.

PROCTOLOGY: ITS QUALIFICATIONS AND PROGRESS

CHAIRMAN'S ADDRESS

FRANK C. YEOMANS, M.D.
NEW YORK

Near the end of the last century a national association in gastroenterology and another in proctology were organized. Since then both groups have functioned continuously and successfully.

In 1916, mainly through the persistent efforts of leaders of these associations, the American Medical Association officially recognized both specialties by establishing the Section on Gastro-Enterology and Proctology. Today we meet in the twenty-fifth annual session. The eminent success of the section has fully justified its creation. Through the untiring efforts of a qualified personnel under zealous leaders these special fields of medicine have developed progressively and are now established on a sound scientific basis.

Briefly, the primary functions of any medical specialty are:

1. Scientific. The development of the specialty itself by scientific research and investigation and clinical observation.
2. Educational. (a) Teaching its elemental principles to undergraduate and graduate students, (b) the training of competent young doctors who contemplate taking up the specialty and (c) dissemination within the profession, by the written and spoken word, of useful knowledge which can be safely and effectively applied to practice.
3. Service. Supplying the highest type of medical service to the patient, which after all is the chief objective of medicine.

This program places a heavy but just responsibility on every association of specialists.

Our two special branches are concerned with the alimentary tract and its associated apparatus. Gastroenterology is essentially medical while proctology is chiefly surgical.

Speaking particularly for proctology, what qualifications should those possess who would enter this field, which may be defined as that of the bowel distal to the ileocecal valve.

To qualify properly in proctology one should enter the specialty through the door of general surgery. The essential personal qualifications for any honest specialist worthy of the name are the three I's: Intelligence, Industry, Integrity.

Intelligence and scientific attainment may be gaged in fair degree by personal interview and examinations.

for example those required for fellowship in the American College of Surgeons or for diplomate in surgery.

Integrity, however, is a moral quality which transcends all others. Without integrity the patient may be exploited and the specialty discredited.

It is generally recognized that many more adequately trained, ethical proctologists are needed in many sections of the country. The two agencies that can best solve the problem are the medical schools and the general hospital.

The curriculums of the undergraduate medical schools are sorely taxed. Yet, somewhere in this course each student should have the opportunity of seeing, under the guidance of a competent instructor, the common lesions of the distal portion of the bowel, of doing digital palpations and instrumental inspection of the rectum and pelvic colon and be taught that these procedures should, as a rule, precede roentgen studies.

The surgical staff of the general hospital should encourage a qualified proctologist to organize an outpatient clinic, follow up patients admitted to the wards, have access to the laboratories, and, when he has demonstrated his competence, be permitted to operate in both minor and major conditions within his field. If this reasonable plan were generally adopted, the interns would receive instruction sufficient to avoid the frequent glaring errors in diagnosis and treatment of proctologic conditions after they have finished their hospital residence.

Gastroenterology and proctology are the only clinical specialties represented among the sections of the American Medical Association which do not have independent boards for certification.

The Council on Medical Education and Hospitals has recently approved the action of the American Board of Surgery in regard to the recognition of proctologists. This provides that applicants must first meet the same requirements and pass the same examinations as applicants for certification in general surgery. In addition, applicants for proctologic surgery are required to pass a clinical test to be given by a committee representing this special field. We urge all those who contemplate specializing in proctology to become diplomates of the American Board of Surgery.

PROGRESS IN PROCTOLOGY

Medicine is not static but progressive. The scientific method of advance is usually slow, seldom dramatic, yet a brief survey of some of the advances in proctology during the past quarter century demonstrates that substantial progress has been made and that opinion has crystallized as to the best management of several important diseases.

Anatomy.—A restudy of the anatomy of the anorectum by Milligan and Morgan,¹ and others has clarified the complex musculature of this region and explained the channels through which infection spreads—two important and practical contributions to an understanding of the morbid anatomy of the parts and the surgical procedure indicated for their correction.

Proctosigmoidoscopy.—At long last the value of proctosigmoidoscopy is generally recognized. It is a routine in well equipped clinics but, alas, many hospitals still do not possess suitable equipment or have trained personnel, and all too frequently the procedure is omitted by the general practitioner. The modern

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941

pneumoelectric tube is invaluable in diagnosis (including biopsy); for check-up observation and for treatment (a) with topical applications, (b) for implanting seeds of radon and (c) for surgical diathermy of tumors by fulguration, coagulation or the electric snare.

Roentgenologists as well as clinicians agree that proctosigmoidoscopy should precede a roentgen study of patients having symptoms referable to the distal portion of the bowel because the rectum and the pelvic colon, accessible to palpation and direct inspection, are the sites of about 75 per cent of all tumors of the large bowel. The roentgen ray frequently misses a small intestinal growth within the bony pelvic girdle while it is still small and amenable to early treatment. Moreover, these segments are involved in nearly all inflammatory and infectious conditions of the large bowel. In fact the disease process begins in the rectum in the majority of cases of amebic and bacillary dysentery and chronic ulcerative colitis.

Of course a roentgen study of the remaining colon or entire gastrointestinal tract is essential in many instances. Refinements of roentgenologic technic now frequently show the mucosal pattern and reveal many lesions which were formerly missed. Sigmoidoscopy and a roentgen study are not opposed to each other; on the contrary, they complement each other.

Anesthesia.—Aside from local infiltration anesthesia, caudal anesthesia, sacral-block anesthesia, spinal anesthesia and anesthesia with nitrous oxide-oxygen, ether, cyclopropane, avertin with amylene hydrate and pentothal sodium all have their indications in rectal surgery, and selection should be made appropriate to the individual patient.

Benacol,² the pioneer oil-soluble anesthetic, was originated in my clinic in 1927.³ It stimulated the production of several other similar combinations of chemicals in solution in oil. They are useful for the prolonged relief of pain in acute lesions, notably fissure. The relaxation of the sphincter muscles which follows the proper injection of an oil-soluble anesthetic enables the surgeon to dilate the muscles painlessly, exposing the lesion for topical applications, and thus effect a cure in the large majority of acute fissures of the anus.

Likewise, the injection of an oil-soluble anesthetic immediately after an operation for cryptitis, fissure or hemorrhoids gives in most instances postoperative comfort lasting from a few days to a week.

Pruritus Ani.—In my experience the injection of an oil-soluble anesthetic has afforded temporary or permanent relief in approximately 70 per cent of the many cases of so-called idiopathic pruritus ani in which it has been used.

Hemorrhoids.—Since it has been placed on an ethical and sound scientific basis, the injection treatment of internal hemorrhoids with sclerosing solutions has grown in popularity. The two agents used are a 5 per cent aqueous solution of quinine and urea and a 10 per cent aqueous solution of phenol or 5 per cent phenol in a vegetable oil.

The injection method yields excellent palliation in about 85 per cent of cases of uncomplicated internal hemorrhoids which comprise approximately 50 per cent of all cases. Relief is permanent in many cases, but recurrence in from one to five years in approximately 30 per cent requires another course of injections. How-

ever, one should remember if the patient has no general condition which bars surgery that hemorrhoidectomy is the procedure of choice for the permanent relief of all types of hemorrhoids.

Fistula.—Infection, usually of the anal crypts, is generally recognized as the basis of fissure, abscess and fistula. The latter is usually excised rather than incised, unless the internal opening is so high in the rectum that excision would impair control. In this event, operation in stages is indicated. If feasible, a tuberculous fistula should be excised *en masse* and wide of the disease, preferably with electrosurgery rather than with the scalpel. This technic seals the lymphatics and thus prevents the spread of a tuberculous infection.

Chronic Ulcerative Colitis.—This is still a puzzling problem. More knowledge of food, of nutrition, of the biologic processes and especially of the vitamins may shed light on the obscurity. Chemotherapy is achieving dramatic results in various types of infection. The sulfonamides have proved their worth in many cases of chronic ulcerative colitis. These experiences give promise that a more effective therapy than is now available will be developed for this serious disease entity.

The possibility of amebiasis should be ruled out in every case of nonspecific chronic ulcerative colitis by a careful sigmoidoscopy which reveals the pathognomonic lesions in early cases and frequently establishes the correct diagnosis, although the laboratory examination of the stools is negative.

Joseph Felsen, after extensive clinical observation and laboratory research, has emphasized the role of bacillary dysentery in the causation of chronic ulcerative colitis. To date, this theory has not received wide acceptance.

Stricture.—A wholly new concept of the etiology of inflammatory stricture of the rectum has arisen from the work of Durand, Nicholas and Favre in 1913⁴ and of Frei in 1925.⁵ Syphilis and gonorrhea have been relegated to a minor role. Lymphogranuloma venereum is generally conceded to be the etiologic factor in the vast majority of cases. In practically all cases of stricture with proctitis, the diagnosis of lymphogranuloma is established by obtaining a positive cutaneous reaction to an intradermal injection of an inactivated antigen. Frei used human antigen (1925). Grace and Suskind⁶ introduced mouse brain antigen (1934), and recently (1940) Rake, McKee and Shaffer⁷ have provided lygranum-antigen, produced by growing the virus in the yolk sac of the developing chick embryo. Mouse brain antigen and lygranum are comparatively free from the disadvantages of the human product, yet they appear to be at least equal to the Frei test in sensitivity and specificity.

Chemotherapy with the sulfonamides is proving to be a sovereign remedy for control of lymphogranuloma venereum and for prevention of stricture formation. Unfortunately, in most cases the disease has already progressed to the stage of stricture before coming under treatment. Nevertheless, the sulfonamides should be administered for their virostatic effect on the disease, although they exert little or no change in the stricture

itself. Usually the latter can be managed successfully with irrigations of potassium permanganate and biweekly dilation with Wales soft rubber bougies, in progression to number 7.

Resistant cases may require internal longitudinal incision of the stricture at three points (right, left and posterior) with diathermy, to be followed by routine dilation and irrigations. Multiple fistulas occurring with esthiomene or elephantiasis may require colostomy for relief. Rarely a stenosing tubular rectitis is best treated by perineal proctectomy. I did a perineal excision of the rectum on 2 patients having extensive strictures, intractable to other forms of treatment. One was a Negro woman aged 31, the other a white man aged 49. The result was excellent in both instances.

Carcinoma.—The majority of experienced surgeons and many pathologists now believe that the bulk of adenocarcinomas of the large bowel are mediated through adenomas and that their early detection and destruction is the surest measure for the prevention of cancer. Among the many adenomas of the lower part of the bowel which I have removed there were 18 specimens that showed precancerous changes or definite cancer. If the tumor is pedunculated, it is most simply and thoroughly removed with the high frequency electric snare; if sessile, it is destroyed by fulguration or coagulation.

Although definite palliation and a few five year cures have been reported of carcinoma of the rectum treated with irradiation, the results in general have been disappointing. One of the chief reasons for this failure is that the mucosa of the bowel is highly sensitive to the rays while the cancer is very resistant. Moreover, the unfavorable systemic effect of the roentgen rays, especially on the blood and blood-forming organs, tends to lower the vital resistance. As a consequence, the clinical consensus is that surgical excision is the best procedure in all operable cases, that is, if the patient's general condition is such that he can bear a major operation or he can be rehabilitated; second, that the lesion itself is so limited that there is reasonable expectation that it can be completely removed.

Extensive experience with the one stage abdomino-perineal excision of Miles, with permanent colostomy, yields by far the greater number of five year cures than any other for cancer of the rectosigmoid, lower pelvic colon and rectal ampulla. This rectosigmoid segment is the site of about two thirds of all cancers of the sigmoid and rectum. The operative mortality is within 15 per cent in the hands of surgeons competent in this field but is much higher for the average surgeon who sees comparatively few cases. The moral is that some one surgeon on a hospital staff who is especially interested should have the care of these patients so that he may perfect his technic.

Carcinoma situated in the sigmoid 1 or more inches above the pelvic pouch may be resected safely by inverting the distal end and permanent colostomy, more rarely by an exteriorization procedure and later closure of the colostomy to reestablish continuity.

For a rectal cancer, the upper limit of which can be reached by the finger, perineal excision gives excellent results and a very low operative mortality. It is especially indicated in the treatment of obese subjects, the debilitated and the aged.

This brief survey of progress during the last twenty-five years augurs well for the future of proctology.

THE TREATMENT OF MODERATELY SEVERE SCARLET FEVER

A STUDY OF ALTERNATE PATIENTS TREATED WITH SULFANILAMIDE, CONVALESCENT SERUM AND SCARLET FEVER ANTITOXIN

F. H. TOP, M.D.

AND

D. C. YOUNG, M.D.

DETROIT

The value of scarlet fever convalescent serum and scarlet fever antitoxin in the treatment of moderately severe scarlet fever was demonstrated by a control study reported in a previous paper.¹ Early in 1937 sulfanilamide was introduced in this country as a therapeutic agent for the treatment of hemolytic streptococcus infections, and a similar therapeutic study including sulfanilamide was repeated. During the period Aug. 1, 1937 through July 31, 1938 sulfanilamide, convalescent serum and antitoxin were given to alternate patients who on admission to the Herman Kiefer Hospital showed scarlet fever of a moderately severe grade. As in the previous study, the determination of the severity of the condition and the necessity for a therapeutic agent was the responsibility of two resident physicians who had been in the service for more than ten years. They had no part in the choice of therapeutic agent to be used. Whenever antitoxin was in order a serum sensitivity test was performed; if positive, either convalescent serum or sulfanilamide was used and the patient excluded from the series, and the next patient with scarlet fever of a moderately severe type was given antitoxin if the serum sensitivity test was negative. Both convalescent serum and antitoxin were administered in the hospital admitting room, while sulfanilamide was given by mouth as soon as the patient reached the pavilion, a period not exceeding one hour after admission to the hospital.

The sulfanilamide used was obtained in the form of tablets during the early part of the study and later was furnished in powdered form. The doses administered initially and subsequently at four hour intervals, called respectively the initial dose and the maintenance dose, were chosen rather arbitrarily, for there was little information regarding dosage when this study was begun. The dosage shown in table 1 is based on weight and shows both the initial dose and the maintenance dose. At present an initial dose larger than the maintenance dose is unnecessary for infections which are not severe, but during the time that the study was in progress a large initial dose was administered. The patient's weight was roughly estimated and the prescribed dose for that weight was given. The average total dose for all patients treated with sulfanilamide was 12.4 Gm., and the average duration of therapy was six and three-tenths days. The weight of the patient had no influence on the duration of therapy. Sulfanilamide determinations were not determined as a routine because the amount of drug given was too small to warrant its use. In the instances in which the reading was determined, none were found to be above 5 mg. per hundred cubic centimeters of blood.

This study was aided in part by WPA Project 82-4-120.
The sulfanilamide used in this study was furnished by Merck & Co. Inc.
From the Communicable Disease Service, Herman Kiefer Hospital; the Detroit Department of Health, and Wayne University College of Medicine.
1. Top, F. H., and Young, D. C.: Specific and Nonspecific Serum Treatment of Scarlet Fever, *Am. J. Pub. Health* 29: 443 (May) 1937.

The scarlet fever convalescent serum used was obtained from donors who had recovered from the disease within one year of their being bled in the serum clinic of the department of health. The various batches of serum were not tested for antitoxin content, but it is likely that the amount of scarlet fever antitoxin present in each cubic centimeter of serum was not greater than the amount (less than 2 units per cubic centimeter) determined by testing thirty-three batches of serum used in the previous study. Convalescent serum was given intramuscularly, and the dose was 30 cc.

Scarlet fever antitoxin was obtained from the laboratories of the state department of health, and one therapeutic dose of serum (6,000 units) was administered by the intramuscular route.

The therapeutic agents used in this study were given to alternate patients after they were admitted to the Communicable Disease Service. During the year 390 cases of moderately severe scarlet fever were divided equally among the three therapeutic agents used. The method by which the agents were assigned was considered paramount to obtaining comparable groups. The

following characteristics, which should be similar for all treatment groups, were tested for statistical comparability by using the chi square test: distribution of cases by month, by age, by temperature on admission to the hospital, by the day of disease on which treatment was begun and by the proportion of cases in which there were significant associated conditions. The three treatment groups did not differ with respect to the characteristics enumerated and for the purpose of this study may be looked on as similar in all respects except the kind of treatment received.

RESULTS OF TREATMENT

The therapeutic effect of the agents utilized was tested by observing the result with respect to (1) the number of patients who needed subsequent therapy similar to that used in the study, (2) the decline in temperature, (3) the number of patients with complications, (4) the occurrence of complications, (5) the proportion of patients with multiple complications, and (6) the proportion of patients dismissed from the hospital at the end of the minimum isolation period. Duration of the rash was not estimated because it is difficult to evaluate unless based solely on the presence or absence of rash.

AUGMENTED TREATMENT

For purposes of this study only one dose of scarlet fever convalescent serum (30 cc.) and one dose of scarlet fever antitoxin (one therapeutic dose) were administered by the intramuscular route, while the dose of sulfanilamide was governed by weight. It is com-

mon clinical experience to find that some patients with moderately severe scarlet fever need additional therapy. Occasionally, twenty-four hours after admission, the temperature has remained the same as on admission or has risen or the patient's general condition has shown no improvement. Whenever additional therapy was necessary, this was considered as augmented treatment, was so recorded and the case excluded from the study. The number and proportion of patients needing augmented treatment is shown in table 2. It will be observed that but few patients in each treatment group were given additional therapeutic aid. In the convalescent serum group it was necessary for only 5 patients, and the number was 10 and 11 for the antitoxin and

sulfanilamide groups respectively. Convalescent serum appears to advantage, but the differences noted and not significant for a study of this size ($p = 0.29$).² Patients needing augmented treatment were excluded from further consideration in this study, causing slight changes in the totals of the treatment groups.

2. When p is 0.03 or below, differences found are generally considered significant; that is, they are not considered to be due to chance variations.

TEMPERATURE PATTERN

The therapeutic response, as evidenced by an effect on temperature, is shown in table 3. The patients were divided into three groups with reference to temperature: the first, a group in which fever declined to normal or within one degree of normal within twenty-four hours; the second, a group in which fever declined by lysis within a period of five days, a result ordinarily noted in patients with moderate scarlet fever not treated with serum; third, a group in which fever was maintained or in which a temporary drop occurred, followed by a rise within twenty-four hours.

A temperature decline to normal occurred in 75 per cent of patients given antitoxin, in 63.2 per cent given convalescent serum and in 59.7 per cent given sulfanilamide. Among the remaining patients in each treatment group a decline by lysis occurred most frequently among the sulfanilamide-treated group, followed in order by the convalescent serum and the antitoxin-treated group, the respective proportions of each treatment group being 23.5, 16.8 and 10 per cent. Continued fever occurred less commonly among patients treated with antitoxin and sulfanilamide, while convalescent serum showed the poorest results in this respect. The

the proportion in the antitoxin group is highest (39.2), while the convalescent serum group is midway between (32.8): The differences are not significant ($p = 0.09$). No real differences are noted for nonsuppurative cervical adenitis. The number of times that catarrhal or suppurative otitis media developed was small for the entire experience. Catarrhal otitis media occurred with the same frequency in the sulfanilamide and convalescent serum groups but did not occur in the antitoxin group. With respect to suppurative otitis media, the proportion is about the same for all treatment groups. When catarrhal and suppurative otitis media are combined, it is apparent that there is a difference in favor of the antitoxin group, but this is not statistically significant ($p = 0.08$).

The remainder of the complications listed in the table occur too infrequently to warrant comment. Consideration of the entire table must lead to the conclusion that variations in the treatment groups are not striking (table 5).

MULTIPLE COMPLICATIONS

The number of complications per person is shown in table 6. As might be expected with the mild form of scarlet fever now encountered, few persons had more

TABLE 6.—Number of Complications per Person by Type of Treatment

Treatment	Number of Complications per Person				Complications Group			Entire Group	
	1	2	3	4	Number of Persons	Number of Complications	Complications per Person	Number of Persons	Complications per Person

Per cent....	59.0	31.1	8.2	1.6					

differences noted appear to be significant and statistically are borderline ($p = 0.04$). A larger series of cases might demonstrate real differences. However, variation between antitoxin and convalescent serum is not appreciable and bears out past experience.

COMPLICATED CASES

Complications occur in moderately severe scarlet fever more frequently than one would surmise, and this is particularly true of hospitalized cases. This would not be so evident if only major complications, such as otitis media, mastoiditis, cervical adenitis and other less frequent but equally severe complications were solely included. In this analysis all complications incident to scarlet fever infection are considered, even such mild conditions as serous rhinitis and paronychia. Table 4 shows the number of complications in each of the treatment groups, and it is readily apparent that the proportion of complicated cases in the three groups is similar. The advantage shown by sulfanilamide is very slight and not significant.

OCCURRENCE OF COMPLICATIONS

The commonest complications of scarlet fever encountered in hospital practice are, in order of their frequency, rhinitis, cervical adenitis and otitis media. This is borne out in this study by the data in table 5. Rhinitis does not occur with equal frequency in the three treatment groups. The proportion of patients with rhinitis is lowest in the sulfanilamide treated group (26.1).

than two complications each. The proportion of complications in each group is about the same, and differences are due to chance variation ($p = 0.84$).

The table also shows the number of complications per person with complication, which is the same for each treatment group. The number of complications is less than 1 per treated patient and is similar for each treatment group (table 6).

DISMISSAL STATUS

As previously noted,¹ the dismissal status is not a particularly good criterion for evaluation of treatment.

TABLE 7.—Dismissal Status of Cases Admitted to the Hospital

Age	Total in Group			Late Dismissals			Proportion of Late Dismissals		
	S	C	A*	S	C	A	S	C	A
Under 1 year	27	30	37	12	12	21	44.4	40.0	56.8

* S = sulfanilamide, C = convalescent serum and A = antitoxin.
† () = a percentage based on less than 10 cases.

especially if only one dose of serum is administered. Both antitoxin and convalescent serum cannot reasonably be expected to exert much influence on the incidence of complications which occur two weeks after the administration of serum. The same is true in the

instance of sulfanilamide, the administration of which was maintained only during the first week in the hospital. An influence might be exerted on the incidence of complications during the first two weeks of illness, but a large proportion of complications occur during and after the third week of convalescence. However, the soil may be prepared, so to speak, during the first two weeks for what the patient may be exposed to in the hospital during the remainder of his stay. For this reason, data on the dismissal status are included. In the previous study, no difference was noted in the proportion of patients dismissed at the end of the required minimum period of isolation, and in this clinical experiment the proportion of late dismissals in each of the treatment groups (total cases) is practically the same. There are striking differences observed when age is considered, but too much weight cannot be given to the results because of small numbers.

COMMENT

Although the clinical study was completed in the late summer of 1938 and the analysis early in 1939, there was some reluctance on our part to publish the results. Timidity was due not to lack of confidence in the validity of the data or in the manner of collection but rather to the fact that in our hands sulfanilamide appeared to be only slightly less valuable in the dosage given than one therapeutic dose of antitoxin (6,000 units) or 30 cc. of convalescent serum administered intramuscularly. By this time it was already evident experimentally that sulfanilamide did not affect the clinical manifestations or complications directly caused by toxin elaborated by hemolytic streptococci.

In recent years scarlet fever has become a progressively milder disease. Both septic and toxic attacks still occur, but the number is proportionately smaller. The therapeutic agents used in this study would be inadequate in amount for septic and toxic attacks. Moderately severe scarlet fever also occurs less commonly, as shown by the fact that this type represented 37.8 per cent of 10,666 cases of scarlet fever dismissed from the Herman Kiefer Hospital during the five year period 1927-1931, while during the five year period 1932-1936 the proportion of this type among 10,777 dismissals was 21.7 per cent, a considerable decline. Both the organism and its toxin contribute to the clinical syndrome called scarlet fever, but the quantitative effect of each in any given case would appear at best controversial. Antitoxin is valuable in the treatment of moderately severe scarlet fever and is particularly indicated for toxic manifestations. It has been amply demonstrated that scarlet fever convalescent serum is of value in the treatment of moderately severe scarlet fever. Soon after sulfanilamide was used in the treatment of streptococcal infections it was found that it had little effect on toxic manifestations of streptococcus origin. This finding was borne out in early reports. Any value that sulfanilamide might have in the treatment of scarlet fever would likely be due to antibacterial properties, and it is now generally conceded that the effect is bacteriostatic rather than bactericidal.

During the past three years, there have been numerous reports dealing with the use of sulfanilamide in the treatment of scarlet fever. These clinical reports fall into two groups; first, those which include scarlet fever among other streptococcal infections treated and, secondly, those which deal solely with scarlet fever. The

first group does not lend itself to evaluation, while the second group includes few studies which are adequately controlled. The use of sulfanilamide in the treatment of scarlet fever has been reviewed sufficiently often to allow its omission in this paper. We are interested in the fact that there is a difference of opinion concerning the value of sulfanilamide in moderate or moderately severe scarlet fever.

Of all articles published thus far, that of French³ appears on inspection to be the best planned and the most exact in the method of assignment of cases to treatment groups. She finds that the use of sulfanilamide is not justified in the treatment of scarlet fever. The dose used was large and therapy was maintained for the entire period of isolation. However, when indicated, she gave scarlet fever antitoxin on admission to any patient who was thought to require it, irrespective of whether the patient was to receive sulfanilamide or not. Although the number receiving antitoxin in each group was the same, we feel that any therapeutic agent to be tested should be given alone and not in conjunction with another agent, particularly one of such proved value as scarlet fever antitoxin. For this reason we excluded patients with augmented treatment from further consideration in the series. French probably labored under the same difficulty that we did, namely the undesirability (in the eyes of the medical and nursing personnel) of withholding a known valuable therapeutic agent from one half of the cases (controls). We partially circumvented this problem in the previous study by introducing as an unknown serum diphtheria antitoxin one dose of which contained 1,000 units, alternating this with scarlet fever convalescent serum and antitoxin.

In the present study sulfanilamide replaced the diphtheria antitoxin and we feel that, with each patient in the study receiving but one therapeutic agent instead of two, the exact effect of any one can better be determined. For this reason the present study is submitted. Additional studies are needed to confirm or refute the findings because clinical evaluation cannot feasibly be based on deaths but must rely on differences in behavior in cases in which recovery occurred and this entails a few large studies or many well conducted small ones. When results of therapy are so nearly alike, as noted in this study, it is impossible to state that any of the therapeutic agents used are of value, unless the impression is based on other clinical or experimental studies. In the previous study 30 cc. of convalescent serum and one therapeutic dose of antitoxin (6,000 units) given intramuscularly were found to be of equal value in the treatment of moderately severe scarlet fever. The same statement applies in this study.

SUMMARY AND CONCLUSIONS

1. During the one year period Aug. 1, 1937 through July 31, 1938 a series of 390 patients with moderately severe scarlet fever were treated under control conditions with (a) sulfanilamide, (b) scarlet fever convalescent serum and (c) scarlet fever antitoxin.

2. Status-on-admission factors known to influence the course of the disease, such as (a) the month of attack, (b) age, (c) temperature on admission, (d) day of disease on which treatment was begun and (e) proportion of cases presenting significant associated conditions, were similar and not significantly different for the three treatment groups.

3. French, Jane O.: The Sulfanilamide Treatment of Scarlet Fever. *J. Hyg.* 39: 581 (Sept.) 1939.

3. The results of this study indicate that there is no great difference in the therapeutic effect in cases of moderately severe scarlet fever when sulfanilamide, convalescent serum and antitoxin are administered in the dosage used. Antitoxin and convalescent serum give better results than sulfanilamide, but the differences are not statistically significant.

4. In a previous study, 30 cc. of scarlet fever convalescent serum and one therapeutic dose of scarlet fever antitoxin (6,000 units) gave equally good results when administered by the intramuscular route. Their similarity in value in the dosage cited is again demonstrated.

5. No attempt is made to explain the results obtained. The study is presented as an addition to the literature on the subject.

Taylor and Hamilton Avenues.

HEALTH EDUCATION

AN APPRAISAL

DONALD B. ARMSTRONG, M.D., Sc.D.

Third Vice President, Metropolitan Life Insurance Company
NEW YORK

Perhaps the time has come, as is apt to be the case periodically in most fields, for a fresh orientation as to what in general we mean by health education. There are still those in public health who see little or no value or scope in health education. There are also those, in increasing numbers, who appear to think that health education and public health are practically synonymous terms—coextensive in range and content. Between these two extreme views, what is health education's real status?

Parenthetically, let me make it clear at the start that I am attempting to appraise the relative importance of health education in the public health field as compared with other elements. I am not attempting an analysis from a psychologic or other angle, of what constitutes effective health education or what technics will or will not arouse real interest and action. This is another story, though indeed a very important one.

We might, in a few words, remind ourselves of the origin in time and in its interrelationships of the health educational aspect of our public health program. Recently Dr. W. W. Bauer has said that "All public health workers are health educators whether they know it or not." This is more nearly true today than at any time in the past, and it is at least a laudable aspiration. Still, there are even now some essential workers in the public health field who have little or nothing to do with health education, such as the laboratory man typing sputums in pneumococcic infections or examining blood specimens in sulfonamide therapy. What these men are doing is basic in the public health program but really cannot be called health education. The same would apply to the engineer operating a water purification or sewage treatment plant, and in the main to the research work that developed the antigen for the pneumococcus vaccine or that originally purified the antibody in serum therapy. These men may do extremely important work and still not undertake even professional teaching activities, let alone popular health education.

As a matter of fact, health education played little or no part in the beginning eras of modern public

health. It came into play, for obvious reasons, as public health evolved into the period of preventive medicine, where the attainment of disease preventive objectives (particularly in a democracy) is dependent on individual motivation. But back in the sanitary era the typhoid epidemics and other sanitary catastrophes of that earlier time were in fact the "educators" of the citizens and of the voters, inducing them, among other things, to appropriate adequate funds for the collective provision of sanitary measures, such as those that insure a safe water supply. But the community collectively did the job for the individual.

On the other hand, beyond the safe use of water to restrict the transmission of disease, the community cannot, by law, compel the individual to the proper constructive use of water for the attainment of certain hygienic and physiologic advantages. It cannot make him take enough water daily to meet the chemical needs of the body (though the importance of this has been somewhat overemphasized by health education); it cannot compel him to bathe with sufficient frequency, although here too health education has exaggerated the importance of the measure; it cannot even compel him to wash his hands with hot water and soap before he eats and after toilet. These uses of water must depend on personal information, on individual motivation—in fact, on health education (or, perhaps, on custom built on the commercial advertising of sanitary equipment, soap, and so on), though it must indeed be recognized that individual initiative won't be effective unless the water and the necessary utensils also are available.

In any event, we are now in the age of personal hygiene and preventive medicine, where health education comes fully into its own. Yet this modern phase of public health grew out of and is based on sanitation and is, in fact, the superstructure of public health. Health education is an essential part in that superstructure. How is it built into that framework? How much of a part does it play in the functioning of this whole public health mechanism? Let us ask ourselves these and a few other concrete questions.

WHAT CAN REASONABLY BE CLAIMED FOR HEALTH EDUCATION?

Well, there are some perfectly reasonable claims as to its accomplishments, though these claims are often confused, and the evidence is almost always fairly intangible. Yet we are all convinced that health education not only has important direct products to its credit but some by-products of outstanding importance.

By way of illustration, let us look for a moment at the diphtheria prevention program. Certainly health education of the lay public has contributed materially to the mortality improvement for this disease. Throughout the whole of 1940 Toronto, Ont., and Newark, N. J., two large cities, went without a single case of this disease. New York State, including the city and upstate area, with over 13,000,000 population, had several consecutive winter months in 1941 without a death from diphtheria. The million and more weekly industrial policyholders of the Metropolitan Life Insurance Company in the Pacific Coast and Mountain states went through the first eight months of this year without a diphtheria death. Certainly all of the literature, films, exhibits and lectures have played a big part in these accomplishments. Personal initiative by physicians, parents, teachers and others has been influential. Yet many

other elements have entered into the picture, such as the daily work of the private medical practitioner, the doctor's increasing use of prophylactic measures in his practice, the establishment of clinics, the production of biologic products and their distribution by communities, the postgraduate instruction of physicians with reference to antitoxin therapy as well as immunization and the like. While in fact the whole "struggle" has been in general educative, yet it is difficult in a situation of this kind to say just how much lay health education specifically has done. It can however be incidentally pointed out that, while it has been endeavoring to educate the public, it has also had a material effect on the medical mind as well. Many physicians first heard of the Schick test through lay contacts or through the perusal of literature primarily intended for lay consumption. This might be noted as a by-product of lay education.

One might take another example—the Framingham Tuberculosis Demonstration, where the tuberculosis death rate has declined from 121 per hundred thousand prior to the demonstration to 12.5 in 1940. Never before in the history of public health was a population so intimately and thoroughly exposed to health education as were the people of Framingham from 1916 onward. All conceivable educational channels were used and all important points in tuberculosis control stressed. The private medical practitioner participated wholeheartedly, and the public responded with a high degree of cooperation and understanding. Health education was an important factor in this program. Yet many other factors also were involved, even though health education may have had, directly or indirectly, something to do in securing and enhancing the effectiveness of each of them. I have in mind not only adequate appropriations but such essentials as the employment of full time medical staffs in schools and industries, the provision of adequate bed capacity for active cases, the proper direction of first class medical staffs in good sanatoriums, the establishment of local x-ray diagnostic equipment and milk pasteurization. There were obviously many basic items of sanitation and community equipment playing a part—brought about to some extent through health education and made more effective by health education but distinctly not in themselves health education.

IS IT EVER POSSIBLE ACCURATELY TO MEASURE HEALTH EDUCATION?

The agency with which I am associated, namely the Metropolitan Life Insurance Company, has carried on for years an extensive health educational program among its industrial policyholders. In this program it has used nearly all available devices, has had a fairly adequate budget and has enjoyed the cooperation of an exceptional instrument of education, namely the company's agency force in its contacts regularly with millions of homes. This work has now been going on for about thirty-two years. The results are to some extent measurable and are also quite favorable. It would seem that this health education program has borne fruit.

If the life expectancy at birth of these industrial policyholders is compared with that of the general population, it appears that since 1911 the policyholder group has gained about seventeen years in life expectation, as compared with about ten years for the country's population in general. It has also been calculated that the figure for lives saved in 1939 alone is approximately

112,000 in excess of the lives that would have been saved if the industrial policyholders had experienced only the mortality improvement since 1911 that has characterized the general population of the country. When this experience is broken down by causes of death, and when attention is paid particularly to those diseases at which health education has been especially aimed, we find, for instance, that since 1911 there has been a 92 per cent improvement in diphtheria mortality in the general population of the United States and a 95 per cent improvement in this industrial policyholder group—an excess policyholder improvement of 3 per cent. Without giving all the details, I may say that similar comparisons show an excess improvement in pneumonia of 7 per cent, in tuberculosis of 10 per cent, in diseases of the puerperal state of 17 per cent, and in total accidents of 24 per cent.

Of course, this insured group has shared with the general population all of the other influences that have been prevalent in the country in addition to the company's own health educational program. However, there is a complicating factor, and that is the special nursing service provided by the company for acutely ill policyholders and aimed particularly at problems of the industrial insurance group. In this nursing service special attention has been paid to diseases of the puerperal state and communicable diseases, including diphtheria and pneumonia. How much this nursing service, instrumental as it has been in also encouraging adequate medical care, may have influenced this mortality experience, it is difficult to say. Equally difficult is it, therefore, to appraise separately the health educational values.

There is one element in the Metropolitan experience that may be a more direct and more sensitive measure of health education than any of the disease factors cited, and that is the experience with appendicitis. Beginning in 1934 the company initiated an educational program aimed at the prevention of unnecessary fatalities from this disease. This has been carried out by means of literature, advertisements, posters, lectures and news releases. The cooperation of the medical profession, and particularly of the company's agents and medical examiners, has been forthcoming. During this period the company has experienced among its industrial policyholders an improvement in appendicitis mortality of over 30 per cent, and a drop of 40 per cent since 1929. The rate has been declining rapidly and is still declining. (Incidentally, the general population improvement in this period since 1934 has been about 24 per cent.) Other reports, from hospital studies in Philadelphia, for instance, show a decline in perforated appendicitis from 43 per cent in 1928-1929 to 19 per cent in 1937. Moreover, into this picture have come no great new medical discoveries, such as toxoid in diphtheria, serum and chemotherapy in pneumonia, or immunization procedures as in other communicable diseases, although there may have been some modest advances in surgical skill, some stimulus to hospitalization through insurance plans, and, very recently, some experimental use with sulfonamide derivatives and other products in the treatment of peritonitis following perforation. No important changes have taken place in diagnostic or therapeutic practices. One might say that practically the only outstanding new factor in the picture, in relation to the other constants or changing minor variables, has been this intensive educational program. Perhaps, therefore, this might be offered as a fairly good example of a health educational accom-

plishment. Practically all other examples that one can think of share the limitations pointed out not long ago by Dr. Martha C. Hardy, who stated that "Evaluation technics in health education . . . are very limited. . . . These results, and reports from other investigations, while interesting, seldom permit conclusive answers. They are much more likely to raise questions than they are to produce evidence of the effects of health education."

ARE HEALTH EDUCATORS SOMETIMES CONFUSED AS TO DEFINITION?

I need perhaps quote only one or two examples to indicate positive answers to this question. One who has contributed a great deal indeed to physical education recently said that "Health education in schools has three major lines of effort: health service, healthful living in the school, and health instruction." I expect most readers will agree that this does not seem to be a very accurate or clear concept. This leader then goes on to explain what he means by each of these divisions of effort. He says, for instance, that under "health service" he means "examination and protection of children." Under this heading he includes also the search for defects and structural disease and the examination of "attitudes, personality traits and responses, as well as defects and organic health disturbances." In other words, he lumps under one of these phases of "health education" all of the professional, technical, medical and clinical procedures in the schools. Obviously these procedures are not health education, though of course they should be health educational.

IS THE SIGNIFICANCE OF HEALTH EDUCATION SOMETIMES EXAGGERATED AND ITS SCOPE MAGNIFIED OUT OF PROPORTION TO REALITY?

The attitude reflected in the foregoing quotations would seem to be one example of a clearly affirmative answer to this question. Others will probably occur to most of us. If I may carelessly employ metaphors, many have been impressed with the tendency on the part of health educators to "put the cart before the horse" or at any rate to confuse the part for the whole. This may be in part due to two factors:

1. Professionally trained people have often approached health education through highly specialized channels, such as those of physical education. They consequently seem to acquire an out of focus view or a tangential rather than an inherent relationship to the public health fields.

2. For nonprofessionally trained workers, health education has been the back door into the barn of preventive medicine, as easy access for those with no specific technical training for any of the basic jobs in public health and preventive medicine. In spite of this, or perhaps because of it, those entering by this door seem disposed to think that the barn and the door are one and the same thing.

An illustration of this confusion and of this identification of the part with the whole seemed to be implied in a recent request from a health educator that a paper be prepared on the subject "Do the Recent Draft Figures Show Serious Gaps in Health Education?" This arresting suggestion involved, apparently, two misconceptions: (1) that health education can ordinarily be measured by its effects and (2) that health education was the important if not the only factor (or should

have been) in determining the results of the current draft figures, as compared with those of twenty-five years ago.

Of course, the draft figures will be turned in all directions. Those who want to use them for the further extension of socialized services are already loudly lamenting the allegedly poor state of the nation's health (which really was never better) and will no doubt find ammunition that can be diverted to this end. Those who wish to "view with alarm" will point out that more are being rejected today than in 1917, but this comparison is unwarranted, because today we started with the idea of careful selection for training, using higher standards and more delicate methods. More are being rejected for certain causes, such as ear and dental defects. From this it may be claimed that our whole health effort and our machinery for medical care have been ineffective and that health education has completely failed, yet we know this to be a gross misinterpretation. On the other hand, those disposed to take a favorable view will find plenty of supporting evidence. In fact, the tuberculosis figures have already been pointed to as evidence of the value of health education in this intervening period, in view of the rejection in 1917 of higher percentages for pulmonary ailments than in 1941. Very probably health education has played a part in this situation, but how important also have been a great variety of other factors, such as isolation and hospitalization, improvements in x-ray technic and fluoroscopy, pneumothorax therapy, milk pasteurization, advances in nutrition, and higher economic living standards?

Confusion of definition, magnification of importance and misunderstanding as to measurability sometimes seem to lead to an attitude that assumes not only that all health activities are a part of health education but also to the belief that only health educational activities should be tolerated in schools and elsewhere. For instance, one finds in an editorial in a recent number of the *Journal of School Health* a statement that "All health services practiced in schools can and should be educational." No one would quarrel with that. The editorial goes on, however, to imply its acceptances of the corollary that "if the service cannot be made educational it should not be in the schools at all." This is to ignore certain basic essentials in school health programs. We should not forget that the medical examinations of children in schools is done in part to apply technical skills with the object of discovering early disease, of finding defects that can be corrected, of controlling the spread of communicable diseases and of disclosing personal practices that have a bearing on the physical and mental status of the child. The basic service here is a clinical, epidemiologic and physiologic one. It has some value, whether educational or not. Of course, these procedures should always be used for constructive health educational purposes, but that is not their sole or primary purpose though it may become their greatest measure of utility in highly sanitized communities.

HAS HEALTH EDUCATION SOMETIMES BEEN MISLEADING AND OBSTRUCTIVE?

It seems likely that there are examples warranting an affirmative answer to this question. Many will remember the great emphasis of two decades ago on toothbrushing as a means for the prevention of dental decay. Not only was the child taught in school cer-

tain highly detailed technics as regards toothbrushing, but whole schools and squads of children were mobilized in playgrounds and elsewhere and exposed to toothbrush drills, thus overemphasizing this already exaggerated point. The same amount of energy, time and funds diffused nationally through this program, if concentrated into a limited field of research, let us say into the relationship of nutrition or of heredity to dental caries, might have produced constructive results, and at any rate probably would not have been largely wasted.

HAS HEALTH EDUCATION SOMETIMES FAILED?

If health education has failures in its record, it is probably because of misapplication, such as in the aforementioned toothbrush drill era, or it is because, through its own megalomania, it "bites off more than it can chew." An example in the latter category may well be the experience in the matter of disease control in the province of Quebec. In this province death rates from controllable disease, such as pneumonia, tuberculosis and diphtheria, still remain much higher than in the other Canadian provinces or in the United States. These diseases refuse to respond to educational attack. Such control efforts under identical epidemic conditions are much less successful than elsewhere.

By way of illustration, let us take the recent influenzal pneumonia outbreak, which early in 1941 spread across both Canada and the United States, from west to east. In most parts of the two countries, in spite of the increase in influenza with accompanying increase in the incidence of pneumonia, the pneumonia death rate for this period in 1941, as compared with 1940, did not increase but actually decreased, evidently reflecting the effectiveness of serum therapy and chemotherapy. In contrast, in Quebec province there was not only an increase in influenza and pneumonia incidence, but a sharp increase in pneumonia fatalities—quite obviously for the reason that medical practice and public health procedures in this province are backward and that the province does not yet have, in comparison with other areas, these therapeutic advantages in meeting the pneumonia problem.

Now, what will bring pneumonia under control in Quebec province? Health education? What will make modern diagnostic and therapeutic procedures available? Health education? It may help a little in all directions but it will not solve the problem. As a matter of fact, a great deal of health education is being done and has been done in this province. The Metropolitan Life Insurance Company has concentrated on these questions there even to the extent of preparing health education material in the native language. It insures a larger percentage of the population there than elsewhere. It has a higher industrial policyholder mortality rate there than elsewhere. It and other agencies have tried health education, but that does not meet the need.

What is needed is a whole set of basic facilities and services, such as better equipped and staffed medical schools, improved medical curriculums, better undergraduate and postgraduate medical education; better basic training for nurses, more competent public health training for nurses; nonpolitical public health administration; more adequate appropriations, more adequate supplies of biologic products for use free or at cost; a greater awareness on the part of physicians of the preventive medical point of view; more adequate hospital

facilities; better and more numerous physical plants for clinical services, and so on. While health education has a bearing on all of these things and will help to make them available and to get them used when available, it will not in itself produce them or solve the problem without them. Under present conditions in this province its efforts are largely wasted and doomed to partial failure.

HOW SERIOUSLY SHOULD HEALTH EDUCATORS TAKE THEMSELVES?

From the foregoing the implication would seem to be that we should not take ourselves too seriously. We should remember that health education is one of a number of things. Health educators are probably feeling an unwarranted anxiety in these trying times. They are for instance, watching the draft figures anxiously. They have "staked everything" on producing results through education, and the present generation, coming up for examination, is really their first child to reach maturity. Nobody knows, because we have never had any adequate method of measurement, just how well he has learned his lessons. Health educators, according to their disposition, are now anticipating feeling very good or very bad when the figures begin, in final form, to come through. Yet they should remember that they are dealing with one factor only, with one of the most intangible of elements and the hardest one to measure. Should conditions prove to be better or worse, there would be nothing to crow or to weep about from the angle of health education or from any other single angle in the picture, as too many elements share this responsibility.

WHAT THEN IS THE CHARACTER OF HEALTH EDUCATION AND ITS RELATION TO PUBLIC HEALTH?

While the element health education is not all important, it is important to all other elements in public health and preventive medicine as practiced in the modern community. Health education helps to create its associate units essential in a basic health program. It should permeate all of these related services and influences. As a matter of fact, without these concrete services, such as medical examinations in schools, clinic facilities in health centers and examination services in industry, health education remains a highly intangible, theoretical, abstract and largely futile commodity. It finds its substantiation, its realization in its relationship to these practical services. It is visualized, precipitated, brought out of the realm of theory by its contact with its basic service colleagues. It therefore has a creatively reciprocal relationship with the other elements in public health. It enhances their value and reality and finds its own realization through them. It is the one element that contributes most to making the whole substantially greater than the sum of its parts.

HAS HEALTH EDUCATION A UNIQUE SIGNIFICANCE?

While health education is one of many elements in the public health picture, it is different in character from any of these elements. It is not just "one other thing" in preventive medicine. It is or should be an ingredient in all the basic services in preventive medicine. All other services should be shot through with it or illuminated by it. It is actually or potentially inherent in all of them. It might perhaps be called the

enzyme in the process. In the digestive process are involved the mucous membrane of the gastrointestinal tract, the cells of the villi of the intestinal walls, the blood vessels, the cells of the blood stream, the musculature and the constituents of the food itself. These all have to be there and all have to do their part. They constitute the basic essentials. But their efficiency and thoroughness are stimulated and released by the effect of the digestive enzyme on them. Now in public health, within the school walls for instance, health education bears a similar relationship to the doctor, the nurse, the clinic, the laboratory and the other personnel and equipment. Perhaps the analogy has flaws—doctors are apt to do some good in just examining and treating children, with little or no health educational motive, while digestion won't take place at all without the enzyme. Nevertheless in schools, in health centers and clinics, in industry and in all phases of the public health program it is the enzyme "health education" that implements and activates its associate forces in the cooperative effort to prevent disease, promote health and build the vigor and endurance demanded by the stress of living in our time.

All that I have said applies to health education in a democracy—in a free society, where initiative, judgment and individual decision and enterprise still function—where it is still possible and indeed necessary to try to inform and persuade people as to what they should do for the benefit of themselves and the community. On the other hand, health education and indeed all education as we know it are of disappearing importance in most of the rest of the world, where the "educator," turned propagandist, tells the people what to do, although even in Germany the chief propagandist is said recently to have lamented the fact that there were still a few people in his country who could not be told how to act and live and think.

Health education, and indeed all education as we think of it in America, is not only an essential ingredient in the free democratic process. Today, more than ever before, it must play a vital part in sustaining and justifying our way of living. As Hutchins has said, "What the world needs, what this country must have, is free minds . . . minds informed by principles derived through human experience through the ages; minds that are open no matter what waves of change beat upon them." Such education, in all fields, including our own, is in the long run our chief defense against the growing trends toward socialization, collectivism, dictatorship and totalitarianism, both abroad and at home.

1 Madison Avenue.

The President's Birthday Ball.—The support of research through public subscription such as the President's birthday ball or the Christmas seal campaign of the National Tuberculosis Association presents special features worth comment. It would be a splendid tradition if each president could designate on what disease the proceeds of the homage tendered him should be spent. Then with an occasional change of presidents we should see a reasonable distribution of support to different forms of research. But the limitation of this form of support is that the machinery of securing the funds may become effective more rapidly than the organization to expend them, and the desire for specific results may exceed the probable returns. A better procedure than usually characterizes public subscriptions would be for each of the specialist societies to nominate research councils entrusted with the expenditure of funds collected by public subscription.—Gregg, Alan: *The Furtherance of Medical Research*, New Haven, Conn., Yale University Press, 1941.

AIR EMBOLISM IN ARTIFICIAL PNEUMOTHORAX

THOMAS R. JONES, M.D.

HOUSTON, TEXAS

AND

JESSIE A. LOCKHART, M.D.

SANATORIUM, TEXAS

Of all the complications of artificial pneumothorax therapy, air embolism is the most alarming and most dangerous. Its occurrence is sudden and without preceding signs or symptoms, as it is in reality an accident. Its results either are instantaneous or appear in a short time.

Rogers, while irrigating the empyema cavity of a small girl in 1864, observed an attack characterized by pallor, unconsciousness and clonic convulsions with recovery after twenty-four hours. While diagnosed as pleural eclampsia it may be logically assumed from the description of the attack that this was a case of cerebral air embolism.

Brandes¹ in 1912, while attempting to outline an empyema cavity with bismuth paste, accidentally demonstrated the mechanism of air embolism. On injection of the paste, the patient became unconscious and was suddenly seized with fatal convulsions. On postmortem examination bismuth was found in the vessels of the cerebral cortex and brain stem.

AIR EMBOLISM IN PERIPHERAL CIRCULATION

Every physician and intern who has given intravenous injections knows that often small quantities of air have been introduced into the peripheral veins with no untoward effect.² This can be explained on the basis that the amount of air injected was small and its injection into the circulation slow. This allowed for its absorption in the vascular lung tissue. Thus, 3,910 cc. of air was injected slowly into a dog over a period of eighty-seven hours before death occurred.³

On the other hand, fatal air embolism does occur during operations on the neck and in manual loosening of placentas. Here the quantity of air admitted is large and its entrance into the circulation rapid. Experimental work has shown that the fatal dose of air for a 150 pound (68 Kg.) man would be about 525 cc., if injected rapidly into the peripheral circulation.⁴ Death is the result of failure of the right side of the heart due to blocking of the pulmonary circulation and interference with ventricular output of the heart due to air bubbles.⁵

PHYSIOLOGY

Curtillet,⁶ in experimental work on animals, has shown that air bubbles do not reach vessels of a caliber of less than 30 microns; that is to say, they never reach capillaries. Arrested in the endarterioles of 30 to 40 microns in diameter, they are rapidly absorbed. Air and oxygen are absorbed at about equal rates of speed. Carbon dioxide is absorbed more rapidly than either. Air bubbles injected into the peripheral circulation, barring such anatomic defects as a patent foramen

ovale or a ductus arteriosus, are completely filtered out in the vascular system of the lungs and are never found in the vulnerable arterial circulation.

AIR EMBOLISM IN ARTERIAL CIRCULATION

It has been demonstrated that the injection of moderate amounts of air into a systemic vein leads to embolism of the smaller vessels of the lung with no harmful defects. On the other hand, relatively minute quantities of air injected into the pulmonary vein produce severe reactions or death. This is because the air passes from the vein, through the left side of the heart into the systemic arteries. Experimental work⁷ indicates that the lethal dose of air thus entering the arterial circulation of a 150 pound man is about 37.5 cc. This depends on how rapidly air emboli obstruct vital cerebral or coronary arteries.

From clinical observations it seems that cerebral embolism is the most frequent cause of death in these cases. However, Moore and Braselton, working with cats, found that death occurred from coronary obstruction in every case, regardless of the position of the animal. Within a second or two after injection of air into the animals, air bubbles were seen descending the coronary arteries. The air filled both the left and the right arterial tree. This complete obstruction of the arteries led to extreme dilatation of the ventricles in five to six minutes, though under artificial respiration the animals made convulsive respiratory movements at this time indicating that the respiratory center was still functioning.

Wever⁸ demonstrated by numerous experiments on rabbits, dogs and cats the effects of introducing air directly into the carotid arteries and found that the symptom complex resulting coincides with that sometimes observed in air embolism from pneumothorax therapy. At times he could produce air emboli with less than 1 cc. of air, while on other occasions the injection of 2.3 cc. of air failed to produce symptoms. Depending on the amount of air introduced, he observed variations from mild tremors and mild disturbances of cardiac and respiratory action to sudden death. The milder effects resembled what we believe has been incorrectly termed pleural shock.

AIR EMBOLISM VERSUS PLEURAL SHOCK

Many physicians⁹ still diagnose as pleural shock cases in which the syndrome of pallor, nausea, vertigo, convulsive tremors, coma and temporary blindness is present, with complete recovery.

Schlaepfer¹⁰ carried out a series of experiments on the normal pleurae of various animals. He found that stimulation of a normal pleura by mechanical, chemical, electrical and other stimuli did not produce a constant specific reaction by way of the central nervous system as one would expect if the so-called pleural reflexes were the source of the syndrome mentioned.

Capps⁹ repeated these experiments on dogs with an acute pleurisy produced by intrapleural injections of

turpentine and oil contaminated with bacteria. In some of these cases, stimulation of the inflamed visceral pleurae produced no decided change in blood pressure. In others there was a considerable fall of blood pressure, which was sometimes fatal. Capps also stated that during aspirations of pleural effusions in human beings he had purposely irritated the visceral pleura with the end of a trocar and had observed a significant fall of blood pressure. During several hundred aspirations of simple pleural effusions and tuberculous empyemas at the Texas Sanatorium, we have frequently either punctured or scratched the moving visceral pleura with the trocar. In none of these cases have we ever observed syncope or a significant fall of blood pressure from irritation of the visceral pleura.

Introduction of the trocar through the parietal pleura without anesthesia produces excruciating pain; however, after the trocar has pierced and anesthetized the parietal pleura, it may pierce or scratch the visceral pleura without producing any perceptible sensation of pain or discomfort. Shaw¹¹ states that during several hundred intrapleural pneumolyses and thoracoscopies of the chest, both with and without manipulation of the visceral pleura, he has never observed a case of pleural shock or air embolism. During these intrapleural pneumolyses adhesions are severed by the actual cautery, at times while work is being done close to both the parietal and visceral pleurae. If such a mechanism of pleural reflexes through the central nervous system existed, the mechanical and thermal stimulation of intrapleural pneumolyses should certainly produce pleural shock. Apparently the absence of reactions in these cases is due to the fact that the visceral pleura and lung are never actually pierced and there is no chance for cerebral air embolism to occur.

PATHOLOGY

It is often impossible to obtain pathologic-anatomic proof in fatal cases of air embolism because of the fact that minimal and undemonstrable air bubbles introduced in the carotid arteries often cause death.¹² Frequently, however, at autopsy air bubbles have been found in the cerebral vessels of fatal air embolism cases.

Spielmeier¹³ has reported that the first demonstrable pathologic changes in the brain appear about fifteen hours after the air is injected and consist of a beginning liquefaction of brain cells and the encrustation of the fine nets around the ganglion cells. After three to five days, proliferation of glia cells at the site of the diseased nerve cells is very pronounced. These changes are predominantly in the form of islands and there are no bleedings or necrotic softening. About twelve days after the air embolism occurs, large glia cells are seen at the place of the disintegrated cortex cells.

Air embolism is more apt to occur in the pathologically altered lung than in the normal lung because, in the presence of induration and adhesions in the former, vascular contractility is impaired. In the infiltrated portion of the tuberculous lung the pulmonary veins are kept stretched in the rigid tissues and cannot evade the needle as in the healthy tissues. Should the needle injure such a vein, its walls cannot collapse as they would normally.⁸ It is evident that, when to such

an injury a negative pulmonary venous pressure of —7 to —8 cm. of water is added, air may be sucked into such an injured vein from the needle tubing, from the lung alveoli or from the pleural cavity itself. It is not necessary that air should be introduced into the vessel from the outside to produce air embolism.

INCIDENCE

Among 1,869 cases of pneumothorax reported in the literature¹⁴ there occurred 43 cases of air embolism. This is an incidence of 2.3 per cent, or 1 in every 43 cases of pneumothorax. Among 126,547 pneumothorax treatments reported¹⁵ there occurred 96 cases of air embolism. This is an incidence of 0.0758 per cent, or 1 during every 1,318 pneumothorax treatments. Among 142 cases in which the mortality was reported¹⁶ there were 41 deaths. This is a mortality of 28.8 per cent for all cases of air embolism.

At the Texas Sanatorium during the past twenty-three years 115,380 pneumothorax treatments have been given with 19 cases of air embolism. This is an incidence of 0.016 per cent, or 1 air embolism in every 6,073 pneumothorax treatments. During this period in which 19 air embolisms occurred there were 3,036 pneumothorax patients receiving treatments. This is an incidence of 0.62 per cent, or 1 air embolism in every 159 pneumothorax patients. Among these 19 cases there were 7 deaths, a mortality of 36.8 per cent.

REPORT OF CASES

Among the 19 cases of air embolism occurring at the Texas Sanatorium, a fairly complete record was available in 17 cases:

CASE 1.—R. H., a white man aged 25, a clerk, with no history of exposure to tuberculosis, had influenza in December 1940 with poor recovery, followed by malaise, pleurisy and loss of weight. Gradually he acquired a productive cough and by February was raising 4 cc. of mucopurulent sputum daily. Fever and intermittent hoarseness appeared. On Feb. 20, 1941 he stopped work and began observing regular rest hours. On admission to the sanatorium ten days later, fairly extensive involvement of the upper lobe of the left lung was found with no definite cavitation. He was classified moderately advanced (b), and the sputum contained tubercle bacilli. Left artificial pneumothorax was advised, and the initial puncture of 300 cc. of air was given on March 14 with good manometer readings. Next day 400 cc. of air was given with a final manometer reading of 0, —8 (cm. of water). The third refill was given March 18 at 8:40 a. m. As the pneumothorax needle entered the chest the manometer showed a pressure of plus 6 cm. of water. The needle was manipulated and the manometer showed a reading of —12 cm. A few cubic centimeters of air were given and the reading was —8, a few

more cubic centimeters and the reading was —6, a few more cubic centimeters and the reading was —2. The patient became pale, closed his eyes and rolled forward slightly. He became unconscious, the pupils dilated, and the eyes rolled upward. He made three or four feeble, jerking movements of the left arm and then lay still. Epinephrine hydrochloride and artificial respiration were administered. Irregular pulse beats appeared, and these were followed by several convulsive respiratory movements. At 8:55 a. m. both the heart action and the respiratory movements stopped. In all about 50 cc. of air was induced, and the fatal reaction lasted twelve minutes.

At necropsy the left lung was almost completely collapsed by pneumothorax. A single sheet adhesion extended from the apex to the first rib. Three needle punctures with subpleural hemorrhage were seen in the arteriolateral aspect of the lower lobe. Section of the lung showed that one needle tract passed through a 5 mm. pulmonary vein. No air bubbles could be demonstrated in the coronary or cerebral arteries. The heart was contracted and there was about 1 ounce (30 cc.) of blood tinged fluid in the pericardial sac.

CASE 2.—C. H., a white woman aged 19, a student, with no history of exposure to tuberculosis, suffered from malaise and loss of weight in November 1938, and a slight cough appeared. One year later a diagnosis of tuberculosis was made. On admission to the sanatorium, Nov. 21, 1939, her condition was classified as far advanced (a), with extensive involvement of the upper half of both lungs with a small cavity in the left upper lobe. The sputum contained tubercle bacilli.

The right lung improved steadily, and on July 31, 1940 an unsuccessful attempt was made to collapse the left lung by artificial pneumothorax. On a second attempt two days later, 350 cc. of air was introduced with a final manometer reading of 0, plus 2 cm. of water. On the third refill, March 5, the initial reading was —1, —7 cm. of water; 25 cc. of air was given and the manometer read 0, plus 7 cm. of water. The needle was withdrawn, and the patient rose to a sitting position. She complained of feeling weak and nauseated and immediately had a convulsive seizure of the right arm and leg and became unconscious. Both eyes were deviated to the left side. The head was lowered, and artificial respiration was given. She regained consciousness in about ten minutes but complained of blurred vision and severe headaches for the next twelve hours.

CASE 3.—H. G., a white woman aged 23, a housewife, with no known exposure to tuberculosis, had pleurisy in 1937, and after the birth of a child in September 1939 she had malaise and loss of weight. In May 1940 she became ill with a chill and high fever, and this was followed by a productive cough and expectoration of about 30 cc. of mucopurulent sputum daily. Hoarseness, night sweats and indigestion appeared. She remained in bed until her admission to the sanatorium, June 12, 1940. Her condition was classified far advanced (b), with extensive disease, and multiple cavitations in the left lung. The sputum was strongly positive for tubercle bacilli. Left artificial pneumothorax was advised, and the initial puncture was made on June 17 at 9:20 a. m. On the first puncture the pleural space was not located and there was no oscillation of the manometer. A second puncture was done immediately, and the manometer showed a negative pressure of —4 cm. of water. The air was turned on and off twice. The pressure was still —4, but there was no fluctuation of the manometer on respiration. In all, about 25 cc. of air had been injected when the patient closed her eyes, became pale and slumped forward. She became unconscious, and feeble tonic tremors occurred momentarily in the arms and legs. Epinephrine hydrochloride and artificial respiration were given and the head was lowered. The patient improved for a minute and was able to talk. She then became unconscious again. The respiration was gasping and convulsive and the pulse was irregular. The condition rapidly grew worse and the heart action ceased at 9:46 a. m. despite artificial respiration. There was no necropsy.

CASE 4.—E. T., a white man aged 27, a café manager, had been exposed to a tuberculous father. In March 1939 malaise

and slight expectoration appeared. On entering the sanatorium on May 10, 1939 he was classified as having moderately advanced (c) tuberculosis, showing extensive involvement of the left lung with cavitation in the upper lobe of the left lung. The sputum contained tubercle bacilli. Left artificial pneumothorax was advised and 350 cc. of air was given at the initial puncture on May 17. The eighteenth refill of 300 cc. was given on July 21, with an initial reading of 0, —8, and a final reading of 0, —4 cm. of water pressure. The patient felt a moderate pain in the left chest but walked back to his room. Here he became nauseated, dizzy and developed blurred vision and headache. The blurred vision and headache lasted for fifteen hours, when complete recovery occurred.

CASE 5.—J. B. B., a white man aged 27, an oil field worker, with no known exposure to tuberculosis, suddenly had a massive hemorrhage on March 10, 1939. He was given right artificial pneumothorax and went back to work immediately. In August 1939 he began streaking again and this time was given pneumothorax on the left side. He observed no rest hours prior to his admission to the sanatorium on September 17. His condition was classified as moderately advanced (a); there was bilateral cavitation in both apices. The sputum was positive for tubercle bacilli, and there was an anal fistula. Bilateral pneumothorax was continued, and on October 11 the pneumothorax needle was induced into the right chest. Before any air could be given the patient complained of blindness, nausea, chilly sensations, and pains in both arms and the right chest. The needle was withdrawn, and the head lowered. The patient became semiconscious, and tonic contractions of both arms appeared. Little blue cyanotic blotches about 1 cm. in diameter appeared over the right anterior chest and right arm and lasted for about fifteen minutes. Severe headache, nausea and blurred vision continued for twelve hours, followed by complete recovery.

CASE 6.—L. C. L., a white man aged 58, a salesman, with no known exposure to tuberculosis, acquired malaise and loss of weight in March 1937, and two months later a diagnosis of pulmonary tuberculosis was made. On admission to the sanatorium, Aug. 11, 1937, his condition was classified as far advanced (a), showing extensive involvement of the left lung with cavitation and an apical lesion of the right lung. The sputum contained tubercle bacilli. He failed to improve on bed rest, and left pneumothorax was advised. The initial injection of 400 cc. of air was given on September 15, with poor manometer readings. Two days later a second refill of 200 cc. of air was given. On September 20 the pneumothorax needle was induced for a third refill. As the needle entered the pleura there was a manometer reading of —3 cm. of water, but no air was injected. The patient complained of nausea and dizziness. He became unconscious, and clonic and tonic convulsions appeared. The head was lowered, and epinephrine hydrochloride was given. The patient regained consciousness for about one minute, but this was followed by another convulsion. He became cyanotic, and irregular respiration followed; the pulse was regular. Artificial respiration and caffeine with sodium benzoate were given, but the convulsions became worse and the patient died after a reaction of about thirty minutes. No necropsy was performed.

CASE 7.—Mrs. M. W., a white woman aged 25, a housekeeper, whose husband died of tuberculosis in 1925, had malaise, cough and expectoration in October 1935. She entered the sanatorium on Feb. 25, 1936 and her condition was classified as far advanced (b). There was a very extensive involvement of the left lung with an apical lesion of the right lung. The sputum was positive for tubercle bacilli. Left artificial pneumothorax was advised, and the initial injection of 250 cc. of air was given on March 4, 1936. Two days later an attempted refill was unsuccessful because of inability to find the pleural space. Later, on the third attempt to give a refill, the pleural space again could not be located, and after some manipulation the needle was withdrawn. The patient immediately complained of vertigo and nausea. She became unconscious and had generalized convulsions. The head was lowered, and

epinephrine, caffeine and artificial respiration were given. The convulsions increased in severity and occurred more often. The heart beat regularly for sixty minutes and then became irregular and stopped in five more minutes. No necropsy was performed.

CASE 8.—A. L., a white man aged 42, a farmer, had malaise and bloody expectoration in 1922. On admission to the sanatorium, Sept. 3, 1924, his condition was classified as far advanced with total fibrocavernous involvement of the left lung and scattered small lesions over the right lung. The sputum contained tubercle bacilli. Left artificial pneumothorax was begun on November 24 with poor manometer oscillations. The fifth refill was given on December 8. After 50 cc. of air had been injected the patient became unconscious, and generalized convulsions followed. Morphine and epinephrine were given, but the convulsions became more severe, and death occurred in thirty minutes.

CASE 9.—M. W., a white woman, a housewife, had taken pneumothorax in the sanatorium for six months and had been discharged for ambulatory treatment. On a subsequent refill the pneumothorax needle was introduced and about 200 cc. of air had been given. Suddenly the patient became limp and rolled forward unconscious. A few quivering twitches passed through the body, but there was at no time any type of convulsion. The pulse was weak and irregular and soon became imperceptible. The heart ceased beating in about five minutes.

CASE 10.—J. L. D., a white woman aged 30, a housewife, had taken artificial pneumothorax therapy for slightly more than two months, when the needle was introduced for the tenth refill. The manometer showed unsatisfactory oscillations and after 100 cc. of air showed a positive pressure. The needle was withdrawn, and the patient arose to a sitting position. She immediately complained of vertigo and nausea and lay down on the operating table. She became unconscious and was seized by tonic convulsions and lost control of the urinary sphincter. The head was lowered and artificial respiration was applied. Consciousness returned in about ten minutes, but at this time she complained of severe headache and blurred vision. The right pupil was dilated for eight hours and the right side of the face showed the presence of a spastic paralysis for twenty-four hours. The headache remained for forty-eight hours, during which time the foot of the bed was kept elevated.

CASE 11.—T. B., a white woman aged 24, a nurse, had taken artificial pneumothorax therapy for about one year with poor manometer fluctuations, when the needle was induced for a refill. The operator was unable to locate the pleural space, and after some manipulation the needle was withdrawn. Immediately the needle was induced again through the next higher interspace. The manometer showed a negative pressure of —4 cm. of water, but the patient complained of nausea and faintness, and the right pupil became dilated. The patient became semiconscious for two or three minutes, and the pupil remained dilated for about ten minutes. A severe headache lasted for twelve hours, followed by complete recovery.

CASE 12.—Y. R., a woman aged 21, Mexican, a housewife, during the fifteenth refill on Nov. 18, 1940 complained of severe pain at the site of induction of the needle. The manometer showed a negative pressure of —6 cm. of water. After 25 cc. of air had been induced the manometer showed a positive pressure. The patient became limp, unconscious and cyanotic. The respiration was irregular and gasping for five minutes and then became regular. The patient became conscious but complained of feeling weak and faint for the next ten hours.

CASE 13.—M. B., a white woman aged 25, a housewife, had taken artificial pneumothorax therapy with good manometer oscillations for eight weeks. On the tenth refill, after about 50 cc. of air had been introduced, the patient suddenly was seized with severe tonic and clonic convulsions. Bloody, frothy mucus came from the mouth and nose. The patient bit her tongue several times and attempted to swallow it. Artificial respiration and epinephrine were given. The patient remained unconscious for two hours, during which time recurrent convulsions occurred and rectal and bladder sphincter control was

lost. At the end of this period the patient complained of blurred vision for the next twelve hours. Severe headaches persisted for the next three days.

CASE 14.—A white woman aged 23, a housewife, had received artificial pneumothorax therapy for eight weeks. On the eleventh refill the operator had trouble locating the pleural space but after some manipulation of the needle secured a manometer reading of -8 cm. of water. After 100 cc. of air had been given the patient became pale and unconscious and was seized with generalized convulsions. She uttered loud groaning sounds, vomited several times, and blood tinged, frothy saliva came from the mouth. The patient was given epinephrine and artificial respiration, but the convulsions became more frequent and severe, and the patient died in twenty-five minutes without becoming conscious. No necropsy was performed.

CASE 15.—A woman aged 35 had been receiving artificial pneumothorax therapy for three weeks. On the fifth treatment the manometer showed a negative pressure of -8 cm. of water. After 125 cc. of air had been induced, the patient became pale and unconscious. The needle was withdrawn and the end was blood tinged. Generalized clonic convulsions followed; the patient became cyanotic and swallowed her tongue. The pulse was imperceptible, the respiration gasping and convulsive. Epinephrine, ammonia and artificial respiration were given. The patient became conscious in fifteen minutes but complained of blurred vision and severe headaches for three days.

CASE 16.—A woman aged 28 was receiving artificial pneumothorax on admission to the sanatorium in May 1926. On the seventh pneumothorax treatment in the sanatorium she suddenly became unconscious after 100 cc. of air had been given. The needle was withdrawn and the tip was blood tinged. The patient was limp and pale, and no pulse was palpable. The respiration was irregular. Epinephrine and artificial respiration were given. The patient became conscious in ten minutes but complained of exhaustion and nausea for the next twelve hours.

CASE 17.—A white woman aged 27 had a tuberculous empyema. During aspiration and irrigation of the empyema cavity she suddenly complained of weakness, vertigo and severe pain over the precordium and down the left arm. She was semiconscious for about five minutes and uttered loud groaning noises. For twenty-four hours she complained of precordial pains, pain and numbness in the left arm and blurred vision.

TREATMENT

Treatment of air embolism consists in prophylactic and therapeutic measures. Prophylaxis deals mainly with the technic employed in giving artificial pneumothorax treatments. A thorough study by roentgen ray and fluoroscopic examinations will show areas of consolidation, adhesions and cavitation near the periphery of the lung and will guide the operator away from these dangerous areas. The pneumothorax needle should be introduced attached to a syringe of procaine hydrochloride. In this way, once the needle has penetrated the parietal pleura, air can be drawn back freely into the syringe whereas, if the needle has penetrated the lung or an adhesion or is in a blood vessel, on retraction of the syringe plunger frothy blood tinged fluid or blood will be withdrawn. If air bubbles obtained are from the lung they are usually blood tinged and difficult to withdraw. Unless the needle aspirates air freely it should be withdrawn immediately and another puncture site selected. The introduction of the needle should be direct and with as little manipulation as possible.

During refills, free manometer oscillations should be obtained before air is introduced.

If the patient complains of severe pain, nausea or vertigo or other symptoms common to air embolism, the needle should be withdrawn and the patient's head lowered for at least ten minutes.

Once air embolism has occurred, the quicker the air bubbles can be removed from the coronary and cerebral circulation the better the prognosis. Small air bubbles are absorbed spontaneously in a period of ten to twenty minutes, and, if the patient can be kept alive by artificial respiration and stimulants until absorption of the air occurs, recovery will follow. The head should be lowered to an angle of 30 degrees to prevent further cerebral embolism. Epinephrine hydrochloride and caffeine with sodium benzoate are circulatory and respiratory stimulants and aid the circulation in dispersing the air bubbles.

In the event of impending respiratory failure, artificial respiration is necessary.

The head of the patient's bed should be kept lowered for at least half an hour after cessation of symptoms.

Carbon dioxide¹⁷ has been advocated as a substitute for air in the initial and first few pneumothorax treatments. It is absorbed much more rapidly than air and consequently is of less danger if embolism occurs.

SUMMARY

1. Of the 17 cases reported, 10 cases—2, 4, 5, 6, 7, 8, 10, 11; 13 and 14—were apparently due to cerebral air embolism. These were characterized by pallor, partial or complete loss of consciousness, and residual headaches and blurred vision. Among these cases there were 4 fatalities.

2. Five cases—1, 3, 9, 12 and 16—were apparently due to coronary air embolism and presented the symptoms of unconsciousness, cyanosis, irregular heart action, absence of convulsive seizures and presence of convulsive gasping respiratory movements. Three of the 5 patients died.

3. Two cases—15 and 17—presented symptoms of both coronary and cerebral embolism. Neither reaction was fatal.

4. In 9 cases the reaction occurred during the process of inducing air, in 4 cases after the needle was removed, in 3 cases before air was given and in 1 case during the aspiration of pleural fluid.

5. The amount of air induced before the reaction varied from none to 300 cc.

6. The number of air emboli on the various pneumothorax treatments was as follows: one on the first, four on the third, two on the fifth, one on the seventh, two on the tenth, one on the eleventh, one on the fifteenth, one on the eighteenth, three after many treatments, and one during aspiration of an empyema cavity. Half of the air emboli occurred on or before the tenth pneumothorax treatment.

7. The symptoms and signs of air embolism are pallor, dizziness, blurred vision, papillary dilatation and failure to react, ocular deviation, nausea, unconsciousness, tonic and clonic convulsions, mottling of the skin, air bubbles in retinal vessels, paresthesia, precordial pain, irregular respiration, abnormal heart action and residual headache.

8. Clinically, cerebral air embolism seems to occur more often than coronary embolism, but in 35 cats air induced in the pulmonary vein caused death by coronary occlusion without exception.

9. Among the 17 patients who had air embolisms, 11 had adhesions and poor compressions, 5 had good compressions, and 1 reaction occurred on the initial puncture.

17. Moore, R. M., and Braselton, C. W.: An Experimental Study of the Embolic Effects of Air and of Carbon Dioxide, *South. Surgeon* 9: 733 (Oct.) 1940.

CONCLUSIONS

1. Air embolism occurs more frequently in patients with adhesions and poor compressions. Half occur during the first ten pneumothorax treatments.
2. An air embolus occurs once on an average among every 79 pneumothorax patients, an incidence of 1.3 per cent, and once among every 2,104 pneumothorax treatments, an incidence of 0.047 per cent.
3. The mortality from air embolism is about 29 per cent.
4. The treatment consists in lowering the patient's head and giving artificial respiration and stimulants, as epinephrine hydrochloride and caffeine with sodium benzoate.

Clinical Notes, Suggestions and New Instruments

A DEFINITE AND UNIQUE OCCURRENCE OF RAPIDLY FATAL INFECTION CAUSED BY *BACILLUS VIOLACEUS MANILAE*

HERBERT J. SCHATTENBERG, M.D., AND WILLIAM H. HARRIS, M.D., NEW ORLEANS

Considerable skepticism is extant regarding the pathogenicity of *Bacillus violaceus*. It has been generally considered as a nonpathogenic saprophyte having a rather ubiquitous distribution. More careful perusal and consideration of the sparse literature pertinent to this subject reveals, however, that much of the doubt is due to failure of recognition of the fact that many distinctive species exist in the group of which *Chromobacterium violaceum* is the type species. For a comprehensive classification of this group as regards both the cultural and the pathogenic aspect, the reader is referred to the presentation of Ford.¹

Woolley² identified by pathogenicity and by other specific biologic reactions a species of this group producing fulminating fatal infections in the caribao, or water buffalo, which he termed *B. violaceus manilae*.

In the 2 human cases recorded, one by Black and Shahan³ and the other by Soule,⁴ the durations of illness were of nine and fifteen months respectively. In the report of Black and Shahan the patient had seemingly recovered after approximately two months but in the later report of Soule it is stated that the patient of Black and Shahan died after about nine months. The patient of Soule was sick for approximately fifteen months and, although the micro-organism had been obtained in culture from the cervical adenitis present, it was not considered as the cause of the illness until necropsy. *B. violaceus* was then recovered from the heart's blood and the lesions present in the various organs, and its etiologic role appeared established.

The causative micro-organism concerned in the present report conformed in all respects to *B. violaceus manilae*. Certain experimental aspects of the results obtained have already been reported⁵ and the subject matter in extenso is also to be published.

In the present case there occurred a definite invasion of the micro-organism with resultant septicemia and ensuing death within a week. No other factors were present whereby confusion or doubt could arise relative to the causation of illness and death.

REPORT OF CASE

C. M., a Negro youth aged 21 years, admitted to Charity Hospital on Aug. 31, 1940, was lethargic and incoherent, so that no satisfactory history was obtainable from him. His sister stated that on Aug. 29, 1940 it was noticed that he was limping on his right foot and it was thought that he had a thorn in it. She said that he had attempted to remove the thorn with his knife. When he arose the next morning he complained of headache and of pain in the right leg. He appeared "feverish" and after a hard chill he was brought to the hospital.

The patient was well developed and nourished. He was delirious and in moderate pain. The temperature was 104.2 F., the pulse rate 112, the respiratory rate 36 and the blood pressure 86 systolic and 72 diastolic. Examination of the head, neck, chest, abdomen and external genitalia showed nothing abnormal. A small abrasion was noted on the sole of the right foot with accompanying tenderness of the entire right leg. There was diffuse tenderness in the right inguinal region, wherein enlarged, firm, nodular inguinal lymph nodes were palpable. Blood counts showed 3.92 million red blood cells and 26,900 white blood cells. Urinalysis and the blood Wassermann reaction were negative. Blood urea, uric acid and dextrose were within normal limits. Blood cultures were taken which after four days yielded heavy growths of *B. violaceus*. Blood agglutinations for tularemia, typhoid, paratyphoid and bacillary dysentery were negative. During the five days in the hospital the patient's temperature ran between 104 and 105 F. excepting the day before death, when the temperature dropped to 102.5 F. The pulse rate varied from 112 to 140 and the respiratory rate from 22 to 60.

On the fourth day after admission to the hospital the patient had signs of diffusely consolidated areas in the lungs and expectorated blood tinged sputum. His scleras became icteric. The terminal picture was one of pyrexia and circulatory collapse ending in death seven days after onset of symptoms and five days after admission to the hospital.

Treatment consisted of the administration of tetanus anti-toxin, sulfanilamide, infusions of 10 per cent dextrose solution, transfusions of citrated whole blood, sedation, fluids and oxygen.

At necropsy the body measured 175 cm. in length and weighed approximately 180 pounds (81 Kg.). The pupils were round and equal and measured 6 mm. in diameter. The scleras were deeply icteric. Extensive dental caries was seen, with evidence of poor oral hygiene. No unusual cervical or axillary adenopathy was noted. The thorax and abdomen were normal. No scars or lesions of any sort were seen about the external genitalia or perineum. The inguinal lymph nodes on the right side were enlarged, firm and discrete; the nodes on the left showed no gross abnormalities. Both lower extremities were symmetrical, and no edema or swelling could be detected. On the ball of the right foot, just posterior to the fifth metatarsophalangeal junction, there was a superficial area of denudation

Fig. 1.—Longitudinal section of lung showing scattered foci of necrosis of irregular shape and size, more numerous in the upper lobe.

Aided by a grant from the David Trautman Schwartz Research Fund. From the Department of Pathology of Tulane University School of Medicine and the Tulane Service of the Charity Hospital of Louisiana.

of the cornified epithelium measuring 2 by 2 cm. No especial inflammatory reaction was present surrounding this area. The abdominal cavity presented no gross abnormalities. The pleural cavities contained 20 to 25 cc. of serosanguineous fluid. There were numerous firm fibrous adhesions on the right side between the parietal and visceral pleurae. The heart weighed 340 Gm.

Fig. 2.—Sectioned surface of liver in which are seen four white foci of necrosis.

The myocardium was of good tone throughout. The heart valves were normal. The right lung weighed 840 Gm., the left 640 Gm. Just beneath the pleural surfaces of both lungs were numerous elevated yellowish areas measuring from 2 mm. to 1.5 cm. (fig. 1). On palpation these areas were found to consist of irregularly rounded firm nodules. Such nodules were likewise felt deeply throughout all lobes. On cut section these lesions stood out from the normal lung tissue and on pressure exuded a small amount of milky fluid. No areas of cavitation or liquefaction were noted. The bases of both lungs appeared to be the most heavily involved portions. The spleen weighed 500 Gm. and was of a uniformly firm consistency. On cut section the pulp was found to be dark red and very friable; it scraped away easily on the knife. The liver weighed 1,920 Gm. Scattered over its surface were numerous oval yellowish areas varying from 1 to 5 mm. in diameter. On sectioning through the liver substance numerous similar lesions were found deeper in the organ (fig. 2), some of which appeared to have undergone softening with formation of a thin creamy brown fluid. A few areas as large as 1 cm. in diameter were seen which were yellowish and of increased firmness but somewhat poorly demarcated. The pancreas weighed 160 Gm. and appeared normal. The gastro-

Fig. 3.—Section of peripheral portion of necrotic focus in liver shown in lower left portion. Extensive necrosis of liver cells are shown with but little cellular reaction.

intestinal tract presented no gross abnormalities. The right kidney weighed 140 Gm., the left kidney 170 Gm. Both showed only slight swelling and congestion grossly. The brain presented nothing noteworthy on gross inspection. On dissection and inspection of the inguinal lymph nodes on the right it was observed that they measured from 0.5 to 4 cm. in diameter.

They were fairly discrete and were but slightly adherent to the surrounding structures. They were dark gray, and on palpation evidence of fluctuation could be detected. On section a small amount of dark gray purulent material was found in the necrotic centers of the lymph nodes. The surrounding tissues, including the femoral vein, showed no extension of the inflammatory process.

Cultures were procured from the lesions of the lung, liver, inguinal lymph nodes and the spleen.

The anatomic diagnosis was *Chromobacterium violaceum* bacteremia with abscess formation in liver, lungs and spleen, bronchopneumonia; acute hepatitis; acute splenitis; acute lymphadenitis.

Bacteriologic examination revealed growths of *B. violaceum* in all cultures. These were eventually identified as *B. violaceum* *manilae* (Woolley).

In general, the microscopic study of sections of the lesions revealed analogous pathologic changes. In many of these necrosis with little or no cellular response was present (fig. 3). Other foci consisted in greater part of necrosis with varying

Fig. 4.—Section of lung revealing a central focus of necrosis with surrounding edema of the alveoli.

degrees of cellular and fluid exudate. Serum, red blood cells, neutrophils and lymphoid cells of different amounts were present. In the lungs extensive edema and some hemorrhagic extravasation surrounded the necrotic foci (fig. 4).

COMMENT

While much doubt has heretofore existed as to the pathogenicity of *B. violaceum* for the human subject, a review of the present case reveals a definite fulminant, fatal infection caused by this micro-organism. The facts presented are an illness of brief duration with a history of likely exposure to infection, a septicemia with positive blood culture, resultant death and recovery of the micro-organism from the visceral lesions. It is also to be noted that no associated source of confusion by other infection or disease existed.

The proved pathogenicity for lower animals both by injection and by experimental splinter routes of infection have previously been reported.²

The continuity of clinical and experimental evidence supplied through the present case forms an incontrovertible sequence of fatal human infection with *B. violaceum* *manilae*.

We wish to stress the fact that there exists a rather universal acceptance of the predominantly saprophytic varieties of this group with little or no recognition that at least one species is of proved pathogenic nature, namely *B. violaceum* *manilae* (Woolley). Because of this fact it appears probable that when this micro-organism is occasionally recovered in certain infections, although truly the causative factor, it is unjustifiably disregarded.

TULAREMIA IN DOGS

L. F. EY AND R. E. DANIELS, COLUMBUS, OHIO

From the literature on the subject of tularemia we realize that some questions remain undetermined in regard to the susceptibility of certain animals and birds to this disease. For example, it is evident that sufficient evidence has not been produced to place the common dog in the group of susceptible or naturally immune animals. Obviously it can be understood that the material required to study the susceptibility of dogs under natural conditions is not always readily accessible. Consequently investigators interested in this phase of the problem have limited their observations to experimental studies. From the few experimental studies we are given the impression that the dog is only mildly susceptible to tularemia, and other opinions indicate that this animal possesses a natural immunity.

In this communication we are prepared to show that dogs can contract tularemia under favorable natural conditions and that a resultant high agglutination titer for *Bacterium tularensis* can be observed in the blood serum following a comparatively short duration of the disease.

Dr. Edward Francis¹ in all probability carried out the original experimental studies on dogs. In 1927 he fed infected guinea pig tissues to two dogs, one for twenty-one days and the other for twenty-five days. On the forty-second day he performed agglutination tests on the blood serum of the dog fed for twenty-one days and the serum showed a response in a dilution of 1:320. The blood serum of the dog fed for twenty-five days was subjected to agglutination tests after the fifty-third day, and the reaction was positive to a titer of 1:640. Further similar experimental studies were made by Francis in 1934 on 4 dogs that were injected with virulent cultures, 1 of which died of tularemia after fourteen days but the other 3 remained well. The 3 developed antitularense agglutinins of 1:160, 1:640 and 1:1,280 respectively. It is his belief that a dog could not be killed by being fed infected tularemic material but that by enormous dosages of the organism injected subcutaneously an occasional dog will die. He concluded that dogs are only slightly susceptible to tularemia.

The cases in dogs which prompted our investigations were brought to our attention in connection with a human case of tularemia. During a conversation with the patient's brother-in-law on Nov. 15, 1940, one of us (L. F. E.) learned that 3 dogs went hunting with Mr. G. D. and that there was a possibility that the dogs might also be afflicted with tularemia. Our informant minimized the significance of their condition, but the lead gave us the opportunity of investigating the cause of sickness. We wish, therefore, to touch on several salient points of the human case.

REPORT OF CASE

Mr. G. D., a patient of Dr. G. O. Thompson of Alliance, Ohio, went hunting on Nov. 6, 1940, with his 3 dogs. The dogs ran down a rabbit, which they killed. Mr. D. picked up the dead rabbit, tore it in three pieces and gave each dog a portion. The following day, November 7, one of the dogs, the youngest, became ill and on November 8 Mr. D. took this dog to a local veterinarian Dr. George F. Nixon.²

While talking with Dr. Nixon concerning the symptoms of the dogs, Mr. D. expressed the thought that perhaps they had contracted "rabbit fever." Apparently at that time Mr. D. felt normal, or at least he was not aware of having contracted the same infection. According to Dr. Nixon, the 2 other dogs became ill a day or two later and, while none were hospitalized, on examination he found no elevation of temperature but described them as being more or less listless, with little or no appetite.

On November 9, three days after handling the rabbit, Mr. D. became quite ill with chills and fever and on November 11 he was hospitalized. In the hospital when informed that the

2 other dogs were also showing signs of illness, he remarked "Well, that is strange. That rabbit didn't run like a healthy one; maybe it was sick."

From consultant Dr. Perry F. King's record in the hospital, it is easily recognized that Mr. D. was a victim of tularemia, and, as one might expect, the site of his initial infection occurred on the hands. The right hand in this instance showed two lesions of the skin, of a bluish red discoloration. One lesion on the index finger appeared as a large papule.

Blood collected from Mr. D. on November 12 was submitted to the Laboratory Division, Ohio Department of Health, with a request that it be examined for typhoid and undulant fever. Routine agglutination tests for these infections gave negative results. A second specimen taken on November 15, nine days from the date of exposure or six days following the onset of the initial symptoms, was forwarded to us for *Pasteurella tularensis* agglutination test. The blood serum reaction was negative, as were repeated tests for typhoid and *Brucella abortus*.

Although the patient received antitularense serum treatment, he died on the night of November 16, seven days from the date of onset or ten days after exposure to the infection. This, of course, is regarded as a short duration of illness and unquestionably accounts for the failure to obtain a positive *Past. tularensis* agglutination reaction. In other words, while the degree of infection was overwhelming, the time was too short for the development of serum agglutinins.

This case, when considered with respect to the short duration of illness and death, is not without a parallel experience, for it is a matter of record that in 1928 Simpson³ reported a case of tularemia which terminated fatally four days and seven hours after the onset of the illness.

On the information supplied by the patient's brother-in-law we laid plans to obtain blood specimens from the 3 suspected dogs. Dr. Nixon collected the blood and we received the specimens on November 25, nineteen days after the date on which the dogs ate the infected rabbit. It was interesting to note that 4 plus agglutination with *Past. tularensis* antigen was observed in each serum beginning with dilutions of 1:20 to 1:320 inclusive, and 3 plus readings in 1:640. Agglutination was absent in a titer of 1:1,240.

In order to rule out the possibility of nonspecific agglutinations in these dogs' serums, plans were carried out to obtain serum from a sufficient number of presumably normal dogs for control purposes. Dr. Nixon submitted the first control series of 7 specimens between December 2 and 9, all of which were taken from dogs in his hospital. These gave no indication of agglutination response. About the same time we consulted Dr. W. H. Hobbs, of the College of Veterinary Medicine, Ohio State University, for additional control material, and he consented to furnish us with three important series of blood specimens. We emphasized the importance of procuring specimens from dogs owned by hunters or farmers. Our object in making this request was to examine blood from dogs which had the closest contact with game animals, including ticks and fleas. In December 1940, Dr. Hobbs supplied 14 blood specimens and in February 1941 we received 10, a total of 24 specimens. The ages of the dogs ranged from 1½ to 10 years, and approximately twelve different breeds were represented in the group. Six were definitely listed as hunting dogs, 6 were owned by persons living in large cities and 12 belonged to farmers or residents in small towns.

All the control serums were subjected to the same procedure as was the serum in the 3 positive cases, but no evidence of agglutination for *Past. tularensis* was observed in any one of the 24 control specimens furnished by Dr. Hobbs.

At the time the results of the tests on the original 3 dogs were reported to Dr. Nixon it was pointed out that subsequent blood examinations would be essential in order further to substantiate our observations and to learn particularly whether the titer of the serums would show a reduction similar to those found in human cases after a lapse of several months.

3. Simpson, W. M.: Tularemia: Study of Rapidly Fatal Case (Four Days, Seven Hours), *Arch. Path.* 6:553 (Oct.) 1928.

From the Laboratory Division, Ohio Department of Health.

1. Francis, Edward: Personal communication to L. F. E.

2. It was largely through the cooperation received from Dr. Nixon that we were able to carry on the studies presented in this paper, since Dr. Nixon furnished us with the records of the dogs and several series of blood specimens including blood specimens from normal dogs for control purposes.

As one of the concluding steps in this study, Dr. Nixon was asked to collect a second set of specimens from these 3 dogs. On March 28, 1941 we had the opportunity of making the confirmatory observations on these specimens, and, as was to be expected, there was a diminished titer noted in each serum. While the original tests were positive in dilution of 1:640, the highest dilution in which agglutination occurred was 1:80, 2 showing a 1 plus reaction and the third gave no reaction. However, in dilutions of 1:20 and 1:40, 3 plus readings were recorded in all.

The dogs recovered and are alive today. Periodic rechecking of these animals is, of course, highly desirable, and provided the dogs are available we intend to make additional tests of blood specimens.

SUMMARY AND CONCLUSION

1. Evidence is presented to show that dogs may naturally acquire mild tularemia by the ingestion of infected rabbit material.
2. Dogs so infected will develop *Pasteurella tularensis* agglutinins in high titer in less than twenty days.
3. It is suggested that blood specimens from dogs manifesting potential *Past. tularensis* infection be subjected to routine agglutination tests.
4. A man died of tularemia seven days after the onset of illness. The man and his 3 dogs acquired the infection from the same rabbit. The dogs survived.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

TELEX HEARING AID, MODEL 1020, ACCEPTABLE

Manufacturer: Telex Products Company, 1645 Hennepin Avenue, Minneapolis.

The Telex Hearing Aid, Model 1020, is said by the manufacturer to be essentially the same as the Council accepted Model 612 except for a change in the case.

Telex Hearing Aid, Model 1020.

In the Council examination the device was found to consist of one microphone and amplifier unit, one crystal receiver, one 30 volt B battery W. 20, one 1.5 volt A battery 2 E. S. and one leather battery case. The weight and dimensions of the various parts are given in table 1.

BATTERY DRAIN

The A battery current shown was 90 milliamperes, independent of the setting of the volume control. The B battery current was independent of the volume control setting but showed a variation between 0.5 and 1.0 milliampere, depending on the sound intensity being picked up by the microphone.

TABLE 1.—Weight and Dimensions

	Dimensions, Inches	Weight, Ounces
Microphone and amplifier unit.....	4¼ by 2¼ by ¾	3.86
Receiver	Diameter 1, thickness ¾ inch	0.2 (without earpiece)
Battery case with batteries.....	4½ by 2½ by 1¼	11.8

INTERNAL NOISE

The internal noise is not excessively high. The instrument is provided with an auxiliary gain control, with three settings for controlling feed-back. Using a well fitted earpiece, the volume could be set as high as three fourths of full volume without feed-back when the auxiliary control was set on con-

tacts 1 and 2. Set on contact 3, the volume could be turned full on without feed-back. Acoustical gains were measured with these last named settings of the controls.

ACOUSTICAL GAIN

The figures given in table 2 are typical of the increase in intensity levels at the ear of the subject over that at the microphone as shown by audiometric measurements.

TABLE 2.—Increase in Intensity Levels

Normal Ear Threshold at Microphone		Gain		
Volume setting	128	256-2,048	4,096	
		Min.	Max.	
Full on	None	13	43	14 decibels
	40 Decibels Above Normal Ear Threshold			
Full on	?	15	44	25 decibels

ARTICULATION

Syllable and sentence tests with hard of hearing subjects gave satisfactory results.

The Council voted to accept the Telex Hearing Aid, Model 1020, for inclusion on the list of accepted devices.

O. E. M. METER MASK ACCEPTABLE

Manufacturer: Oxygen Equipment Manufacturing Company, Inc., 405 East Sixty-Second Street, New York.

The O. E. M. Meter Mask consists of a gum rubber face piece, nasal or oronasal, adjustable head bands, an expiratory flutter valve, a latex collecting bag, an inspiratory check valve, an oxygen percentage meter, a single stage regulator and 4½ feet of rubber tubing. Inhaled atmospheres enter from the latex collecting bag and directly from the supply tubing, past a one way mica flutter valve, thence via the two lead-in tubes of the nasal masks, or through the one lead-in in the case of the oronasal mask. Exhaled atmosphere cannot reenter the collecting bag but leaves through the flutter valve in front of the nose.

O. E. M. Meter Mask.

Oxygen from cylinders or other sources passes first through a small metal chamber, which may be kept entirely closed or partly opened by turning a disk in which are holes of graded size labeled 40, 45, 50, 60, 70, 80, 90 and one position with no hole, marked 95+. These are designed to draw varying amounts of air along with the oxygen as it flows through a jet into the tube supplying the face piece, or no air when the 95+ position is used, closing the metal chamber entirely.

In the Council's examination the apparatus was subjected to the following tests:

A. The nasal mask was worn by a normal human subject for thirty minutes with oxygen flowing at a rate sufficient to keep the collecting bag from collapsing completely on inspiration (7.5 and 8.5 liters per minute) and with the meter disk set at 95+. At the end of this time, through a tube piercing the mask just below the nostrils, a large sample was drawn by several small aspirations at midinspiration. This sample was then analyzed for carbon dioxide and oxygen concentrations by the manometric method of Van Slyke and Peters.

This procedure was repeated, using an oxygen flow of 7 liters per minute with the meter disk set at 90, with 6 liters per minute and disk setting of 80, with 4.3-4.5 liters per minute and disk setting of 60, with 3-3.4 liters per minute and disk setting of 50, and with 2.4 liters per minute and disk setting

of 40. (In each of these tests a large flow of oxygen with the meter disk set at 95+ was first employed for five to ten minutes to wash out the free nitrogen in the lungs before sampling under the conditions just stated.)

B. Since the oronasal mask could differ from the nasal only in the amount of dead space and rebreathing, it was tested similarly for carbon dioxide concentrations only.

C. The fit of the mask about the nose and mouth was investigated by trial and by holding an open bottle of strong ammonia solution closely below the face piece and having the subject inhale deeply.

D. The face piece with exhalation flutter valve and the supply tubing were boiled for three minutes to test the durability of the seal of the valve parts. These and other parts were subjected to prolonged immersion in red mercuric iodide solution, commonly used for short periods for sterilization of nonboilable catheters.

Following are the results of the foregoing tests:

A. NASAL MASK

Meter Disk Setting	Oxygen in Liters per Minute	Oxygen, per Cent	Carbon Dioxide, per Cent
95+	7.5	87.3	0.076
	8.5	96.8	0.000
90	7.0	67.8	0.000
	7.1	63.5	0.400
	7.0	60.8	0.420
80	6.0	69.4	...
	6.0	74.9	0.260
70 (not tested)			
60	4.5	44.6	0.470
	4.3	39.0	...
50	3	42.3	0.073
	3.4	38.3	0.240
40	2.4	42.8	0.000

B. ORONASAL MASK

Meter Disk Setting	Oxygen in Liters per Minute	Carbon Dioxide, per Cent
95+	8.5	0.06
60	4.5	0.26

C. The masks were easy to fit comfortably for prolonged periods when the head straps passed below the ears. No leaks were detected with the strong ammonia vapor.

B. Boiling the face piece for three minutes did not damage it or the exhalation valve. Prolonged immersion in red mercuric iodide did not harm the flutter valve or any other parts.

The Council voted to accept the O. E. M. Meter Mask for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
THEODORE G. KLUMPP, M.D., Secretary.

ANTIPNEUMOCOCCIC SERUM (RABBIT) TYPE XIV

The Council has accepted types I, II, IV, V, VII, VIII of antipneumococcic horse serum and types I, II, III, IV, V, VII, VIII of antipneumococcic rabbit serum. Recently one manufacturer (E. R. Squibb & Sons) presented Antipneumococcic Rabbit Serum, Type XIV, and, after reviewing the situation, the Council decided that sufficient evidence now exists to warrant the acceptance of this type. The status of the other types of antipneumococcic rabbit serums, on the clinical use of which experience is accumulating, is at present under review and will be made the subject of a Council report.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary.

QUININE DIHYDROCHLORIDE.—For standards see the U. S. Pharmacopeia under *Quininae Dihydrochloridum*.

Actions and Uses.—Quinine Dihydrochloride has actions similar to those of quinine, over which it has the advantage of being more soluble in water. It is used where aqueous solutions of quinine are desired, as for parenteral injections.

Intramuscular and especially intravenous administration of solutions of quinine dihydrochloride should be reserved for cases of severe malarial infection in which oral medication is not feasible. In those cases in which intravenous administration is deemed necessary this solution must be diluted to a concentration not greater than 0.5 per cent.

Dosage.—From 0.24 to 1 Gm. ($\frac{3}{4}$ to $15\frac{1}{2}$ grains) intramuscularly or intravenously as indicated by the severity of the symptoms, age and the like.

The Lakeside Laboratories, Inc., Milwaukee.

Ampuls Quinine Dihydrochloride 0.24 Gm. ($\frac{3}{4}$ grains) in 1 cc., 0.49 Gm. ($7\frac{1}{2}$ grains) in 1 cc., 1.0 Gm. ($15\frac{1}{2}$ grains) in 2 cc. (For Intramuscular Use): Each ampul contains the stated amount of quinine dihydrochloride dissolved in distilled water.

Ampuls Quinine Dihydrochloride 0.32 Gm. (5 grains) in 5 cc., 0.49 Gm. ($7\frac{1}{2}$ grains) in 5 cc., 0.49 Gm. ($7\frac{1}{2}$ grains) in 10 cc., 0.65 Gm. (10 grains) in 20 cc. (For Intravenous Use): Each ampul contains the stated amount of quinine dihydrochloride dissolved in distilled water.

ANTIPNEUMOCOCCIC SERUM, TYPE XIV (FROM RABBITS).—An antiserum obtained from the blood of an animal of the genus *Lepus*, containing predominantly antibodies for type XIV pneumococcus (*Diplococcus pneumoniae*).

Dosage.—Average dose, 20,000 to 100,000 units intravenously. The initial and subsequent doses should be administered in such amount and at such intervals as indicated by the condition of the patient, according to the judgment of the physician. With a large initial dose, fewer units may be curative. The Francis cutaneous test (injection of specific pneumococcic capsular polysaccharide) may be used in conjunction with clinical observations to determine adequacy of dosage.

E. R. Squibb & Sons, New York.

Antipneumococcic Rabbit Serum, Type XIV.—It is refined and concentrated by salting out with ammonium sulfate, the globulin fraction being retained. The final product contains merthiolate 1 in 10,000 and 0.2 per cent of phenol. Marketed in vials containing 20,000 units and 50,000 units each. Included in the trade package is a 5 cc. vial containing 0.05 cc. of the same concentrated rabbit serum diluted in 5 cc. of physiological solution of sodium chloride for the sensitivity test.

THIAMINE HYDROCHLORIDE-SQUIBB (See New and Nonofficial Remedies, 1941, p. 551, under Thiamine Hydrochloride).

The following additional dosage forms have been accepted:
Crystals Thiamine Hydrochloride Squibb. Marketed in bottles containing 1 Gm. of crystalline thiamine hydrochloride, equivalent to 333,333 U. S. P. units.

Solution Thiamine Hydrochloride-Squibb, 10 mg. per cc., and 50 mg. per 25 cc. vials. Each cc. contains in addition 5 mg. of chlorobutanol in sterile distilled water.

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies, 1941, p. 556).

The following dosage form has been accepted:

Ampuls Nicotinic Acid Amide-Breon, 50 mg. in 2 cc. Each 2 cc. contains 50 mg. of nicotinic acid amide in physiological solution of sodium chloride.

Prepared by George A. Breon & Co., Inc., Kansas City, Mo. No U. S. patent or trademark.

NICOTINIC ACID-U. S. P. (See New and Nonofficial Remedies, 1941, p. 555).

The following dosage forms have been accepted:

Ampoules Solution Nicotinic Acid, 10 mg. in Physiological Sodium Chloride Solution, 10 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

Ampoules Solution Nicotinic Acid, 20 mg. in Physiological Sodium Chloride Solution, 10 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

Ampoules Solution Nicotinic Acid, 100 mg. in Physiological Sodium Chloride Solution, 10 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

DEXTROSE (See New and Nonofficial Remedies, 1941, p. 179).

George A. Breon & Co., Inc., Kansas City, Mo.

Ampules Solution Dextrose 50% (W/V), 50 cc. Each ampule contains 50 cc. of a solution containing 25 Gm. of dextrose, U. S. P.

SATURDAY, DECEMBER 13, 1941

THE NATION AT WAR

On December 7 the Japanese attacked the United States. On December 8 the President declared a state of war between Japan and the United States; both the Congress and the Senate of the United States adopted resolutions supporting the action of the President. The mustering of the forces of the United States to meet this attack and to carry on warfare to absolute victory places an immediate and tremendous responsibility on the medical profession. By the time this editorial appears, the Selective Service will, no doubt, have intensified its activities to call an additional half million, if not a million, men. For every thousand men called into service, at least six physicians are required.

Fortunately the medical profession has been alert. Since June 1940 the medical profession has been intensively engaged in standardization of military medical procedures, encouragement and promotion of scientific military medical research and enrolment of medical personnel. Already more than twenty-five thousand physicians have given of their services to the Selective Service. Already more than ten thousand physicians are engaged in military medical service. Additional thousands are associated with the United States Army and Navy Medical Corps, the United States Public Health Service, speeded industry and many other military and quasimilitary activities. Moreover, the Office of Civilian Defense has made the medical profession aware of requirements for its services to the civilian population in times of emergency.

Whenever the medical profession has been called on by our government it has responded whole-heartedly and enthusiastically to the Nation's call. Never has there been raised the slightest doubt of the patriotism of the medical profession. Now comes a new opportunity to respond.

The development of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians places on the medical profession the responsibility for supplying the medical personnel necessary to all the services that have been mentioned. The utilization of the roster in the headquarters of the American Medi-

cal Association gives opportunity to supply all the needed officers and, at the same time, to protect the requirements of medical education and the care of the civilian population.

On December 18 the Committee on Medical Preparedness of the American Medical Association will meet in Chicago together with similar committees representing the dental and veterinarian professions to outline the details of the method by which physicians will be called. The state and county committees on medical preparedness will be utilized in developing complete information regarding physicians available for various types of service. Shortly also *THE JOURNAL* will publish a blank on which every physician willing to serve may indicate the special service for which he is immediately available.

The organization has been made ready; the lines of communication are drawn; confusion need not prevail. When the call comes, physicians who are to serve with the military branches will enroll directly through the corps area commander in each corps area and all of the necessary steps will have been taken to facilitate such enrolment. The President of the United States will find the physicians of this nation ready and willing to meet any demands which the nation may place on them.

THE POTENCY OF DIGITALIS

Elsewhere in this issue (Correspondence, p. 2093) appears a communication from the chairman of the Subcommittee on Biological Assays of the United States Pharmacopeia calling attention to the changes in strength and in method of assay of the digitalis preparations of the next revision of the United States Pharmacopeia. Important to the physician is recognition of these changes and understanding of their significance.

Justification for standardization of medicines lies in the facilitation of the interchange of experience. In successive revisions of the United States Pharmacopeia in past decades certain potent drug preparations have been made to conform to international practice. In the revision now current, the eleventh, effective since June 1, 1936, the strengths of powdered digitalis and tincture of digitalis have been adjusted to conform to the standards of the League of Nations. Those responsible for this decision knew that an increase in the strength of digitalis in use in the United States would result. However, the information apparently did not reach the medical profession generally. Only when experience began to reveal the change did it get the proper publicity. Unfortunately by this time there had developed a controversy over what is to some extent a secondary matter. How much had the strength been increased? The chairman of the Subcommittee on Biological Assays of the Eleventh Revision firmly believed that the increase was about 30 per cent.¹ Others have

1. Edmunds, C. W.: The Potency of Digitalis Preparations of the 1936 Pharmacopeia, *J. A. M. A.* 113: 284 (July 22) 1939.

differed with him, holding that the increase was greater, up to 50 per cent or more.²

Criticisms do not seem to have been offered of the intent of the Revision Committee of the U. S. P. XI to make the digitalis preparations of the U. S. P. conform to international practice. As far as it failed to do exactly what was intended this failure was for technical reasons, centering in part at least around the particular material used as the standard of reference. The Twelfth Revision committee has wisely continued the general policy. Again a reference digitalis powder has been established against which all official digitalis preparations are to be assayed. Although it is this powder that is the legal standard, it has been adjusted to contain the same number of international units per gram as it does U. S. P. XII units. Therefore the tincture of digitalis U. S. P. XII will be of the same potency, for example, as the tincture of digitalis of the British pharmacopeia. This action means that official digitalis preparations will continue to be more potent than those in use during the period prior to 1936.

The U. S. P. XII revision committee has not only adopted a new standard reference powder in place of the old but also has adopted a new method of comparison of digitalis preparations with the official standard. Cats are now to be used for purposes of comparison rather than frogs. Although the communication from the chairman of the Subcommittee on Biological Assays does not discuss the reasons for this change in method it represents apparently recognition of the claims of Gold, Cattell and their associates³ that assays made on cats give results which more nearly parallel the potency in man than those which use frogs. Change from frogs to cats does not, however, involve acceptance of the cat unit. Indeed, the studies of the Cornell group⁴ have shown that it may require 25 cat units of digitalis leaf to digitalize a subject, whereas 3 cat units of "digitaline native" will accomplish the same end. Such studies, of course, have destroyed the value of the "cat unit" as a guide to dosage.

With adoption of both a new reference standard and a new method of assay, confidence of the medical profes-

sion in the uniform potency of official preparations should be increased. However, the communication from the chairman of the Subcommittee on Biological Assays properly emphasizes that confusion will continue unless the profession clearly recognizes that there has been an increase in potency of about 25 per cent over preparations in use prior to 1936.

AIR RAID HYPOIMMUNITY

Hygienists will find material for thought in Pfannenstiel's¹ recent report of the effect of wartime conditions on the general level of immunity among people of western Europe. For a decade Pfannenstiel and his co-workers have studied the variation in the bacteriostatic and bactericidal power of the blood of animals under variable nutritional and environmental conditions.

While they did not assume that variations in serum titer are complete measures of changes of immunity in experimental animals, they did assume that humoral variations are the best available indexes in such studies. The technic adopted for such studies was a modification of the technic endorsed by Wright and Holsen,² a constant volume of defibrinated blood mixed with an arbitrary volume of bacterial suspension. The

mixture is incubated for twenty-four hours with a control utilizing the same bacterial suspension in melted agar. Comparison of the number of colonies which develop in the two tests gives a ratio which they designated as the "bactericidal index." Thus if 1,000 colonies per unit volume develop in the control agar mixture, while but 200 viable organisms are demonstrable in the incubated blood sample, the "index" (or ratio) is 1,000:200, or 5. An index of 1 thus means a complete absence of bactericidal action. Applying this technic, Pfannenstiel found that the bactericidal index of a rabbit's blood, for example, is often raised thirtyfold (average, from 2.2 to 56.7) within four hours after intravenous injection of neoarsphenamine, with an occasional rabbit showing an increase of as much as one hundred and fifty fold.³

A Call To Service

DR. FRANK H. LAHEY

President of the American Medical Association

The establishment by the government of a Procurement and Assignment Agency properly places the responsibility for obtaining medical personnel in the hands of the medical profession. The success of this agency depends entirely on a few basic features: the complete cooperation of medicine in what even the most doubting must now admit is a truly national emergency; an unqualified willingness to serve the country however, wherever and whenever required; and a firm purpose to establish the fact that medicine intends to maintain its place in the forefront as it always has when a patriotic example is of such significance.

2. Holsen, T.: *Ztschr. f. Vitaminforsch.* 1:3, 1932.

3. Pfannenstiel, W., and Quante, W.: *Ztschr. f. Immunitätsforsch. u. exper. Therap.* 88:1 (May 30) 1936.

In his earlier studies Pfannenstiel used the typhoid bacillus as his test micro-organism.⁴ He found, for example, that a diet of turnips increases the bactericidal titer of rabbits and that three days' inanition had an even more beneficial effect. The latter observation is contrary to previous data reported by Meltzer and Norris,⁵ who found that the bactericidal action of dog serum was static, "no matter whether it was taken from a well fed, overfed or starving animal." Their studies agree, however, in denying a reduction in humoral immunity as a result of moderate starvation. Pfannenstiel afterward tested the effect of quantitative variations in the daily intake of individual food elements. He found, for example, that a moderate decrease in the daily intake of a mixture of the four vitamins A, B, C and D was without deleterious effects. Subnormal blood titers produced by any cause, however, were increased to normal by the administration of relatively large doses of vitamin C. He concluded from these vitamin tests that in rabbits the bactericidal titer and the vitamin C content of the blood stream are interdependent variables, i. e. they vary parallel with each other.

The immunologic effects of low nutritional level and low vitamin intake became of major importance with the outbreak of the present European war. Bimonthly titrations of bactericidal power and vitamin C content of human blood were therefore begun early in 1940 in the Hygienic Institute, Marburg, Germany. During the first six months the vitamin C content of the blood of selected hospital personnel varied from 2.54 to 14.4 mg. per hundred cubic centimeters. The bactericidal titers of the same individuals varied from 1.00 to 5.04, staphylococci being used as the test micro-organisms. The most obvious fact was the complete lack of parallelism between the vitamin C content and the bactericidal index. The highest recorded bactericidal titer (5.04) was associated with a relatively low vitamin content (5.24 mg.), while the highest vitamin titer (11.46 mg.) was accompanied by low humoral immunity (1.36). The conclusion drawn from these data is that the bactericidal power and the vitamin C content of human blood are independent variables. Partial vitamin C starvation, therefore, has not apparently had deleterious effects on immunity among persons in central Europe. A low total food intake may even be beneficial in conquered countries, since in rabbits from three to five days' total inanition increases the resistance to microbes.

In order to explain observed fluctuations in individual resistance to bacteria, Pfannenstiel called attention to the repeated nocturnal air raid alarms during July and August, with the resulting overwork and loss of sleep. Following each sleepless night half of the selected hospital personnel showed a lowering of bac-

tericidal titer. In 1 case the previous index (5.04) fell two thirds (i. e. to 1.53) following a nocturnal air raid alarm. In a second person there was a complete loss of previous bactericidal power. It may or may not be a coincidence that the second person developed a staphylococcal infection during August, the period of air raid alarm hypoinnunity. Insomniac depression of bactericidal titer was not noted in those who had an opportunity to sleep during the daytime following the night raid.

Disregarding the evident propaganda motivation of this research, evidence of the lack of parallelism between vitamin C intake and bactericidal immunity (or the relatively small amount of vitamin C necessary to maintain maximum humoral efficiency) is of basic clinical interest. Evidence of an insomniac depression of natural immunity is a belated confirmation of a belief long held by physicians. Whether or not data drawn from selected hospital personnel are applicable also to the regional population was not tested by the Nazi investigators.

Current Comment

COLOSTRUM CUTANEOUS TEST FOR PREGNANCY

Several tests have been proposed for furnishing an early reliable diagnosis of pregnancy. An immunologic test, depending on a local cutaneous reaction, has been especially sought. However, thus far only biologic tests are considered reliable. Recently Falls, Freda and Cohen¹ reported a method of cutaneous testing which is claimed to be 98 per cent accurate in pregnant women and 96 per cent accurate in nonpregnant women. In this test a preparation of colostrum is injected into the skin. A faint reaction or none at all is apparent in pregnant women, while the nonpregnant react with a prominent wheal typical of an allergic response. This reaction appears within one-half hour, according to the authors. They tested 358 known nonpregnant women and 265 pregnant women at the time of their report. The test has already been commercialized by G. H. Sherman, M.D., Inc., and physicians are being circularized with the statement that the test is accurate and dependable in the hands of any physician. In view of lack of evidence supporting the results of the original investigators, this premature exploitation is deplored. Physicians may well maintain a skeptical attitude toward the promoter's advertising claims until the original work of Falls and his associates has been adequately confirmed. In this regard complications seem to have developed, as Weisman and Snyder report, in the October issue of the *American Journal of Obstetrics and Gynecology*, page 738, a wide margin of error in the diagnosis of pregnancy by the use of this test. The well established biologic tests need not yet be abandoned.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE

Office of Civilian Defense Needs Two Physicians Immediately

The United States Public Health Service requires at once two physicians, aged 45 to 60, for important duties in connection with the Office of Civilian Defense. If found suitable, these physicians will be offered commissions in the Reserve Corps of the United States Public Health Service in the grade of Senior Surgeons with pay and allowances of the grade corresponding to that of Lieutenant Colonel in the Army or Commander in the Navy. As soon as commissioned, they will be ordered to active duty and directed to report to the Chief Medical Officer of the Office of Civilian Defense. Duties in general are to represent the Medical Division of the Office of Civilian Defense in the Sixth and Seventh Defense regions (this corresponds to the Sixth and Seventh Army Corps areas), study the Office of Civilian Defense program, interpret the medical program to the state and local defense organizations, maintain contact with state and local defense organizations, establish and maintain liaison with governmental and other medical and health organizations in that area, also liaison with the district public health service offices and inspect emergency medical field units in local civilian defense organizations. Active duty will be for the duration of the emergency. Applications should be sent directly to the Executive Officer, Procurement and Assignment Service, New Social Security Building, room 5654-ODH, Fourth and C streets, Washington, D. C.

FORTY-TWO MORE NEW NAVY MEDICAL OFFICERS

The U. S. Navy Department, Washington, D. C., has announced the appointments of the following forty-two physicians as assistant surgeons in the medical corps of the navy to rank as lieutenants (junior grade):

ANDERSON, D. F., Mount Vernon, Ill.	JOHNSON, Frank G., Omaha.
BAKER, W. S., Jr., Detroit.	KULCZYCKI, Edward, Scranton, Pa.
BELL, John P., Annapolis, Md.	LAWRENCE, Richard, Jr., San Francisco.
BURT, Charles W., Detroit.	LEIGHTON, Herbert T., Boston.
CAREY, John E., Kenmore, N. Y.	LOWMAN, E. W., San Diego, Calif.
CLEMENT, Conrad C., Babylon, N. Y.	LYONS, Harold A., Brooklyn.
DASLER, Theodore W., Deer Park, Wis.	MACKBY, Maxwell J., New York.
DAY, Lawrence C., Grayslake, Ill.	MANN, B. F., Jr., Hartford, Conn.
deTARNOWSKY, G. O., Bartlett, Ill.	MILLS, Dawson A., Pittsburgh.
DOUGHERTY, William J., Washington, D. C.	MOORE, Jack D., Montclair, N. J.
DUNN, John C., Brooklyn.	MURPHY, John M., Portsmouth, Va.
EISBERG, Harry B., Staten Island, N. Y.	NIFOROPULOS, J. A., Schenectady, N. Y.
ENGLE, Paul R., Petoskey, Mich.	ORR, Robert B., Brooklyn.
FALK, Victor S., Wauwatosa, Wis.	RICKERD, Charles L., Seattle.
FRANTZ, Winthrop S., Sacramento, Calif.	SHAFIROFF, Charles, Jamaica, Ind.
GARNETT, R. W., Jr., Emory University, Ga.	SPAULDING, E. M., New Albany, Ind.
GULLEDGE, W. H., Wadesboro, N. C.	STUCK, Jaul L., Jonesboro, Ark.
HUNTER, William L., Emory University, Ga.	UMIKER, William O., Buffalo.
JACOBY, Jack M., Detroit.	WHITE, W. A., Jr., Pearl Harbor, Hawaii.
JARDON, F. J., Philadelphia.	WHITELY, Ralph D., Washington, D. C.
JARRETT, Thirl E., Norfolk, Va.	WOOD, Norman L., New York.

TYPHOID VACCINE OUTPUT INCREASED 800 PER CENT

Typhoid-paratyphoid vaccine is made at the Army Medical School in the largest laboratory of its kind in the world. The planting and harvesting rooms, made of monel metal and glass, are sterilized with live steam. During the various steps of vaccine making the chambers are sealed, and conditioned air sterilized by washing and passing through ultraviolet light is pumped in under positive pressure. All the typhoid-paratyphoid vaccine required for use by the Army, the Navy, the Civilian Conservation Corps and other federal departments is made at this laboratory, which at peak production can provide one and a half million doses of the vaccine every week. During the last fiscal year the output was increased over 800 per cent.

PLAN TO RELIEVE SHORTAGE OF NURSES

To relieve the shortage of nurses in hospitals, clinics, public health and field nursing agencies, the American National Red Cross and the Office of Civilian Defense, Washington, D. C., have jointly undertaken a project to train 100,000 volunteer nurses aides, with whose assistance graduate nurses may extend their services to many more patients. The volunteer aide will work under the supervision of a nurse in performing certain nontechnical tasks in order that graduate nurses may be released for highly technical duties.

The local office of Civilian Defense and the local chief of Emergency Medical Service in communities where the program for training nurses aides is undertaken will assist the Red Cross and the Civilian Defense Volunteer Office in enrolling desirable applicants for training as nurses aides and will assist local chapters to make arrangements with general hospitals to serve as training centers. The first half of the course of instruction, consisting of lectures and demonstrations, will be given in the Red Cross Chapter Hospital or other suitable place, while the second half of the course will be given in a hospital selected by the Red Cross and the Office of Civilian Defense as a training center.

The Red Cross has outlined in its publication "Chapter Organization and Administration of Red Cross Volunteer Nurses Aides Corps" the duties of nurses aides which will be subject to the approval of individual institutions. Among other activities, the nurses aides in the hospitals may take care of personal belongings of patients, make beds, feed helpless patients, clean dressing trays, take patients to and from treatment rooms, help with the admission and discharge of patients, care for ambulatory patients, take care of linen closets and of rubber goods, and in dispensaries and clinics may serve as interpreters in foreign languages, dress and undress children, clean and put away instruments, help weigh and measure, assist in taking physicians' notes and help with inventories.

The Office of Civilian Defense, Washington, D. C., has prepared a syllabus of the courses to be given nurses aides, and the American Red Cross has published a Guide for the Training of Volunteer Nurses' Aides, and copies of these are available from local Red Cross chapters or from Regional Civilian Defense Offices.

Nurses aides are to serve without remuneration. The time for the course of instruction is eighty hours. After the first thirty-four hours of the course the aides will wear the uniform with insignia, described in the Guide for the Training of Volunteer Nurses' Aides. Membership in the Nurses Aides Corps requires the aide to be between 18 and 50 years of age when

enrolled, in satisfactory physical condition, a graduate from high school or equivalent. One hundred and fifty hours of service must be given in each calendar year, preferably in a three months period, and the first one hundred and fifty hours must be spent in hospital wards before assignments to clinics and field nurses' organizations. In time of war or other national emergency, aides must be prepared to serve whenever and for as long a period as needed.

BALANCED MEALS FOR SOLDIERS

A master menu, containing all the necessary nutritional requirements for an active soldier and ample variety and quantity of foods, is under preparation by the Army Quartermaster Corps. It will be divided into twelve units, one for each month, containing submenus for every day in the week. The November series was sent out to all Corps Area Commanders. The menus can be used as prepared or adapted to local needs. On the basis of the master menu, monthly menus will be prepared for use in Army posts, camps and cantonments.

The master menu is prepared with the average soldier in mind. He is of medium height and weight but, being engaged in strenuous activities, is hungrier than the average civilian of the same build. The average number of calories daily per man is about 4,500. The menus call for more minerals than meet the requirements of the Nutritional Committee of the National Research Council: iron in excess of 20 mg., phosphorus 2.2 Gm. and calcium 1.1 Gm. The vitamin A total daily is about 7,000 international units, vitamin C 115 mg., vitamin B₁ (thiamine hydrochloride) 3 mg. and vitamin B₂ (riboflavin) 3.1 mg.

Care is exercised to insure that the soldier shall not get a surplus of starchy foods at any one meal. Peas, for example, are not served with corn or beans, nor potatoes with macaroni or spaghetti. Where canned fruits and vegetables are listed in the menus, fresh fruit and vegetables should be substituted if they are available, according to the locality. The following is a typical menu from the master menu for a November day:

Breakfast	Dinner	Supper
Orange	Barley soup	Spareribs
Assorted cereal	Soft roast beef	Boiled potatoes
Fresh milk	Creamed potatoes	Buttered cabbage
Cheese omelet	Spinach	Cinnamon buns
Lyonnais potatoes	Pickled beet salad	Bread and butter
Bread and butter	Bread and butter	Coffee
Coffee	Coffee	

REGIONAL MEDICAL OFFICERS FOR CIVILIAN DEFENSE

The Office of Civilian Defense, Washington, D. C., has organized on a regional basis, with regions corresponding to the U. S. Army Corps Areas. A regional director has been appointed for each region with headquarters in the same city in which the corps area headquarters are located. Regional medical officers have been appointed as follows:

First Civilian Defense Region: Dr. Allan M. Butler, 101 Milk Street, Boston.

Second: Dr. H. Van Zile Hyde, 111 Eighth Avenue, New York.

Third: Dr. W. Ross Cameron, 400 Cathedral Street, Baltimore.

Fifth: Dr. William S. Keller, 425 Cleveland Avenue, Columbus, Ohio.

Eighth: Dr. Witten B. Russ, Room 1014, Majestic Building, San Antonio, Texas.

Ninth: Dr. Wallace Hunt, 233 Sansome Street, San Francisco.

These physicians have been commissioned as senior surgeons in the U. S. Public Health Service.

HISTORY OF EXPANSION OF MEDICAL ACTIVITIES DURING THE PRES- ENT EMERGENCY

A history of the expansion of medical activities in the United States during the present emergency is now being compiled under the direction of Dr. John F. Fulton, chairman of the subcommittee on historical records of the Committee on Information, Division of Medical Sciences of the National Research Council. The history will analyze the expanded activities of the civilian and governmental medical agencies from April 1939, when defense expansion began, until the end of the emergency.

According to the *Army and Navy Journal*, November 22, the general history of medical activities during the emergency will be contained in nine volumes, a number subject to change.

Major Gen. James C. Magee, Surgeon General of the Army, has stated that special emphasis will be placed on the history of the Medical Department divisions since April 1939, when an authorized increase in the Air Corps and the forces at Panama signaled the beginning of defense expansion. General Magee has requested Col. Albert G. Love, M. C., retired, to return to active duty to supervise the present medical department history. Colonel Love is organizing the history of the Medical Department since April 1939, which tentatively will be contained in seven volumes, supplementing the nine general volumes.

Colonel Love, who is said to be an authority on analytic histories of the Medical Department, and Capt. Lewis H. Roddis, M. C., U. S. Navy, are co-editors of volume VI of the general nine volume history, which will contain the "Medical History of Individual Operations and Engagements." Col. George R. Callender, M. C., is editor of volume II, which will give the history of "Offensive Weapons in Relation to Injury." The only other histories of Medical Department activities are those which are concerned with the Civil War and World War I. The present history, when completed, will make the third analytic work completed and the first to contain an analysis of all medical activities—civilian, military and governmental.

PROTECTIVE PROCEDURES FOR HOSPITALS

Dr. George Baehr, chief medical officer of the Office of Civilian Defense, Washington, D. C., has appointed the following subcommittee of the Advisory Board of the Medical Division, Office of Civilian Defense, to prepare recommendations on protective procedures for hospitals in the event of belligerent action:

Dr. Robin C. Buerki, director of hospitals of the University of Pennsylvania, Philadelphia, chairman.

Dr. Willard C. Rappleye, commissioner of hospitals, New York.

Dr. Asahel J. Hockett, superintendent of Touro Infirmary, New Orleans.

Dr. Anthony J. J. Rourke, medical superintendent of Stanford University Hospitals, San Francisco.

Dr. Joseph Turner, director of Mount Sinai Hospital, New York.

Dr. Huntington Williams, commissioner of health of Baltimore.

The subcommittee held its first meeting in New York on November 8. With Dr. James M. Mackintosh, former chief medical officer of the Scottish Ministry of Health, as a guest to advise the group, measures for preventing or minimizing damage to buildings, handling of casualties, evacuation, provision and protection of supplies, and training of personnel for specific duties in case of bombing were discussed. The basis for discussion was a study made by a committee of the American Hospital Association on physical defense of hospitals. It is expected that a report will be issued jointly by the hospital association committee and the committee representing the Office of Civilian Defense.

The basic organization for rescue work in a given area consists of three essential groups with a central control, police, rescue and fire services, air raid precaution control and medical service.

HUGE REFRIGERATORS FOR ARMY FOOD SUPPLIES

Some of the mammoth army ice boxes will hold enough perishable food—meat, butter, eggs, fruit and vegetables—to feed a division of about fifteen thousand soldiers for two weeks. Recently a quartermaster statistician observed in one of these ice boxes 50 tons of meat, 6 tons of butter, 8,000 dozen eggs and, among other items, 25 tons of fresh fruits and vegetables.

HEALTH EDUCATION CONSULTANTS TO BE ASSIGNED TO DEFENSE AREAS

The rapid growth in industrial and governmental production has caused unusual concentrations of population and increasing health problems. To assist state, county and local health officials in coping with these problems, the U. S. Public Health Service is planning to appoint health education consultants to various defense areas. The positions, paying \$2,600 to \$3,899 a year, will be filled through the open competitive examination process and the Federal Civil Service Commission has just issued the

examination announcement. A written test will not be given, but applicants will be rated on their qualifications as shown in their applications and corroborative evidence.

Appointees will work with local health officers and their staffs, advising them as to methods and procedures of health education, such as individual instruction through interview, group instruction through discussions, talks, lectures and other educational technics. To qualify for the positions, applicants must have completed a four year college course, including or supplemented by special study—or, for the assistant grade, experience—in public health. In addition they must have had experience in

public health education work coordinating the activities of all organized health groups in a community for the purpose of promoting a public health program. This experience must have been in a federal, state or official local public health department or in a voluntary agency such as the Red Cross or the Tuberculosis Association.

Applications must be filed with the Civil Service Commission in Washington, D. C., not later than December 11. The examination announcement giving detailed requirements can be obtained at any first or second class post office or at the central office in Washington, D. C.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY WAR DEPARTMENT

The following additional medical reserve officers have been ordered to extended active duty by the War Department, Washington, D. C.:

ARGO, William Lind, 1st Lieut., Oakland, Calif.
BULLINGTON, Bert Montell, 1st Lieut., Ann Arbor, Mich.
FULTZ, George Simeon, Jr., 1st Lieut., Butterworth, Va.
REICHEL, John, Jr., 1st Lieut., Wynnewood, Pa.
ROSEN, Victor Hugo, 1st Lieut., Baltimore
SIEBECKER, Karl LaFollette, 1st Lieut., Los Angeles.

THOMPSON, Robert Philp, 1st Lieut., San Francisco.
WALKER, Douglass Willey, 1st Lieut., New Haven, Conn.
WEINSTEIN, Harry, 1st Lieut., Chowchilla, Calif.
WILLERS, Carl Elmer, 1st Lieut., San Francisco.

Orders Revoked

BERMAN, Lawrence, 1st Lieut., Detroit.
JOHNSON, Carroll Allen, Jr., 1st Lieut., Healdton, Okla.
MICKEL, Arthur A., 1st Lieut., Benicia, Calif.
RYAN, Bernard F., 1st Lieut., Ahwahnee, Calif.
SCHILDHAUS, Andrew I. E., 1st Lieut., Burlington, Vt.

CORRECTION

War Department.—The following names of medical reserve officers were erroneously published as "relieved from active duty" in THE JOURNAL, September 6, under the Ninth Corps Area. These names should have been published under "War Department" as "ordered to active duty": Major Albert Guernsey Clark, San Francisco, and Lieuts. Samuel S. Blankstein, Milwaukee; Irving Lawrence Greenberg, Atlanta, Ga.; John Joseph

Manning, Chicago; John Edward Naugle, Denver; Ernest Boris Newman, Brooklyn; Phosa David Nutter, Russellville, W. Va.; Samuel Sidney Platt, Chicago; Reno Russell Porter, Brookline, Mass.; Peter Albert Reiersen, Chicago; Owen Bernard Royce, Oklahoma City; Thomas Robert White, Redlands, Calif., and William Luther White, Philadelphia.

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, First Corps Area, which comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut:

CHAIT, Sidney A., 1st Lieut., Middletown, Conn., Fort Banks, Mass.
DEL CAMPO, Dante, 1st Lieut., Lynn, Mass., Westover Field, Mass.
CORRIGAN, Francis V., 1st Lieut., Providence, R. I., Windsor Locks, Conn.
CRISCUOLO, Joseph A., Jr., 1st Lieut., New Haven, Conn., Fort H. G. Wright, N. Y.
HARRIS, Oliver J., 1st Lieut., Boston, Westover Field, Mass.
LAMB, Francis D., 1st Lieut., West Warwick, R. I., Windsor Locks, Conn.

MORRISON, Jonathan I., 1st Lieut., Waban, Mass., Westover Field, Mass.
PATTERSON, John C., 1st Lieut., Boston, Manchester, N. H.
SIMON, Norman, 1st Lieut., Lawrence, Mass., Westover Field, Mass.
WALKER, Donald A., 1st Lieut., Worcester, Mass., Army Air Base, Bangor, Maine.
YAVAROW, Mully Millin, 1st Lieut., Everett, Mass., Manchester, N. H.

Orders Revoked

BRIER, Hyman D., 1st Lieut., Bridgeport, Conn.
DOERNER, Alexander A., 1st Lieut., Chelsea, Mass.
FELDERMAN, Jacob, 1st Lieut., Rutland Heights, Mass.
PEARSON, Grosvenor B., 1st Lieut., Foxboro, Mass.
SODA, William E., 1st Lieut., Bridgeport, Conn.

SECOND CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Second Corps Area, which comprises the states of New York, New Jersey and Delaware:

ANDERSON, Orrin E., 1st Lieut., Clifton Springs, N. Y., Fort Du Pont, Del.
BERGER, Harold R., 1st Lieut., Elizabeth, N. J., Fort Jay, N. Y.
BLUESTONE, Leon, 1st Lieut., Brooklyn, Camp Claiborne, La.
HELDMAN, Arthur, 1st Lieut., New York, Camp Shelby, Miss.
HOOD, George B., 1st Lieut., Camden, N. J., Fort Bragg, N. C.

LAPIDUS, Bernard, 1st Lieut., New York, Pine Camp, N. Y.
MARRELLA, Louis F., 1st Lieut., Jersey City, N. J., Camp David, N. C.
MOUNTAIN, Edward R., 1st Lieut., Olean, N. Y., Fort Ontario, N. Y.
PISANI, Antonio J., 1st Lieut., New York, Pine Camp, N. Y.
SMITH, Henry T., Major, New York, Camp Wheeler, Ga.
TURNER, Fennell P., 1st Lieut., New York, Camp Claiborne, La.
VON SALZEN, Charles F., 1st Lieut., Kings Park, L. I., N. Y., Camp Upton, N. Y.

Orders Revoked

VALENTE, Michael A., 1st Lieut., Fort Benning, Ga.

THIRD CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Third Corps Area, which comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland:

DEAN, James Seay, Captain, Pennhurst, Pa., Fort Eustis, Va.
GRAU, John Karl, 1st Lieut., Beaver Falls, Pa., Fort George G. Meade, Md.
HAMPSEY, Joseph William, Captain, Pittsburgh, Camp Lee, Va.
HENDERSON, Charles Henry, Captain, Norton, Va., Fort Belvoir, Va.
MASLAND, Richard Lambert, 1st Lieut., Philadelphia, Fort George G. Meade, Md.

MICELI, Joseph, 1st Lieut., Baltimore, Fort Belvoir, Va.
OPPLEMAN, Herman Frank, 1st Lieut., Richmond, Va., MacDill Field, Fla.
PROCOPPIO, James Joseph, 1st Lieut., Shamokin, Pa., Camp Claiborne, La.
RALSTON, Edgar Lee, 1st Lieut., Murrys ville, Pa., Fort George G. Meade, Md.
RANDALL, Robert Stewart, 1st Lieut., Washington, D. C., Fort Dix, N. J.
SAMPLE, Hyde Glenn, Jr., 1st Lieut., Pittsburgh, Edgewood Arsenal, Md.
SCHORNICK, James Curtis, 1st Lieut., Philadelphia, Fort George G. Meade, Md.
SETTLE, William Booth, Captain, Baltimore, Indiantown Gap Military Reservation, Pa.

SINDACO, Mario Secondo, 1st Lieut, Plains, Pa, Indiantown Gap Military Reservation, Pa
SPIEGEL, Herbert X, 1st Lieut, Washington, D C, Fort George G Meade, Md

Orders Revoked

BAILEY, Charles P, 1st Lieut, Philadelphia

The Integrated Course in Anatomy as Related to Licensure

B I Burns, M D, Dean, Louisiana State University School of Medicine, New Orleans

Teaching of Professional Ethics in Medical Schools

Arthur T. McCormack, M D, State Health Commissioner, Louisville, Ky.

Citizenship as Related to Licensure.

Walter E Vest, M D, President, Public Health Council, West Virginia Department of Health, Huntington.

Accelerating Medical Training in Canada

E Stanley Ryerson, M D, Assistant Dean, University of Toronto Faculty of Medicine, Toronto, Ontario.

Industrial Health as Related to Licensure.

C O. Sappington, M D, Executive Director, American Conference on Industrial Health, Chicago

Licensure Problems in the District of Columbia

George C Ruhland, M D, Secretary-Treasurer, Commission on Licensure, Washington, D C.

Have Basic Science Laxis Advanced the Practice of Medicine?

Thomas J. Crowe, M D., Secretary, Texas Board of Medical Examiners, Dallas.

Revision of the Constitution and By-Laws of the Federation of State Medical Boards

T V. McDavitt, Bureau of Legal Medicine and Legislation, American Medical Association, Chicago

Morris Fishbein, M.D, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chicago, will be the guest speaker at the Annual Dinner of the Federation of State Medical Boards on Monday, February 16. His topic will be:

American Medicine and the National Emergency.

THE ATLANTIC CITY SESSION

Motion Pictures in the Scientific Exhibit

The Committee on Scientific Exhibit is arranging a motion picture program for the Atlantic City session. Motion pictures will be shown only in theaters provided for the purpose rather than in the exhibitor's booth. Six or more such theaters will show pictures simultaneously and continuously throughout the week.

Application blanks for a place on the motion picture program may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 165 has passed the Senate and House, providing for continuing in the service of the Army, Navy, Marine Corps and Coast Guard beyond the term of their enlistment those suffering from service connected diseases or injury who are in need of further medical care or hospitalization. S. 1826 has passed the Senate and House, permitting seeing-eye dogs to enter government buildings when accompanied by their blind masters

Bills Introduced.—H. Res. 337, introduced by Representative Celler, New York, proposes to create a committee of five members of the House of Representatives to study, investigate and report to the House on the proposals that have been made for amendment of the Social Security Act, including a proposal to increase the number of persons to be embraced within the benefits of that act so as to include domestics, farm operators, agri-

cultural workers, employees in nonprofit institutions, casual laborers, employees of state and local governments, professional men and women, and other self-employed persons. H. J. Res. 250, introduced by Representative Bloom, New York, proposes to grant permission to Thomas Parran, Surgeon General of the United States Public Health Service, Bolivar J. Lloyd, Medical Director (retired), Howard F. Smith, Medical Director, Herbert A. Spencer, Medical Director, and Gilbert L. Dunna-hoo, Surgeon, all of the United States Public Health Service, to accept and wear certain decorations bestowed on them by the governments of France, Cuba, Chile, Finland and Luang-Prabang. H. R. 6029, introduced by Representative Knutson, Minnesota, H. R. 6055, introduced by Representative Reece, Tennessee, H. R. 6111, introduced by Representative Tibbott, Pennsylvania, and H. R. 6136, introduced by Representative Maciejewski, Illinois, propose to amend section 2800 of the Internal Revenue Code, to authorize the Commissioner of

Internal Revenue to make a refund of the distilled spirits tax, at the rate of \$1 per gallon, to any person who has used distilled spirits, produced in a domestic registered distillery or industrial alcohol plant, in the manufacture or production of an article intended for use for nonbeverage purposes, subject to certain limitations. H. R. 5827, introduced by Representative Sauthoff, Wisconsin, proposes to require a mental examination of the accused prior to trial of any charge by Army general court martial. H. R. 6030, introduced by Representative Kunkel, Pennsylvania, proposes to amend an act to provide books for the adult blind by increasing the annual appropriation from \$275,000 to \$350,000, by authorizing the purchase of periodicals in addition to books, and by providing that not less than \$2,500 of the sum allocated for books and periodicals in raised characters shall be expended for the publication in braille, for the exclusive use of the deaf-blind, of the magazine of the American League for the Deaf-Blind known as the *Bulletin Board*. H. R. 6069, introduced by Representative Hook, Michigan, provides that after March 11, 1941 all members of the armed forces of the United States shall be entitled to the same benefits awarded to members of the armed forces of the United States as under the World War Veterans' Act of June 7, 1924. H. R. 6106, introduced (by request) by Representative Rankin, Mississippi, proposes to provide liberalized benefits for disabled American veterans of the World War and their dependents. This bill, among other things, provides that in the administration of laws pertaining to veterans, retired officers and enlisted men of the Army, Navy, Marine Corps and Coast Guard, who served

honorably during a war period as recognized by the Veterans' Administration, shall be entitled to hospitalization and domiciliary care in the same manner and to the same extent as veterans of any war are now or may hereafter be furnished hospitalization or domiciliary care by the Veterans' Administration. H. R. 6135, introduced by Representative Lanham, Texas, proposes to authorize an additional appropriation of \$150,000,000 to construct community facilities in defense areas, including hospitals, health centers and clinics. H. R. 6138, introduced by Representative Clason, Massachusetts, provides that any person claiming to be a citizen of the United States at birth, in whose case no official record of birth is available, may apply to the Commissioner of Immigration and Naturalization for a certificate of citizenship.

DISTRICT OF COLUMBIA

Change in Status.—H. R. 5694 has passed the House and has been reported to the Senate, proposing to prevent the sale of unwholesome food in the District of Columbia. A similar bill, S. 2045, was introduced by Senator McCarran, Nevada.

Bill Introduced.—H. R. 6097, introduced by Representative D'Alesandro, Maryland, provides that the National Hospital Service Society, Incorporated, shall be considered to be a fraternal organization and shall be permitted to do business without further license or permit, exempt from the provisions of the insurance laws relating to the District of Columbia.

MEDICAL ECONOMIC ABSTRACTS

MEDICAL CHANGES IN BRITAIN

Bombing and overcrowded insanitary shelters led the British to anticipate epidemics, says Ritchie Calder in *John O'London's Weekly* (April 25, 1941). But when a body of American experts under Prof. J. E. Gordon of Harvard arrived they found that the expected epidemic had failed to materialize.

In fact, the shelters had a lower disease rate than the average for the country. And the country as a whole, apart from the war epidemic of "spotted fever," or cerebrospinal meningitis, due mainly to the bringing together of young people under dormitory conditions, in the army and other ways, could show a bill of health comparable with the good years immediately before the war.

Although the war has not yet brought epidemics, it has created problems in the organization of medical services. There have been many proposals for changes in the panel system, which this writer says "no one would dare to pretend . . . has been satisfactory." It is generally agreed that the "approved society" system is wasteful. The British Medical Association has proposed to extend the panel system to dependents, but the first effect of this would be to make nearly double the sales value of existing practices, which would compel physicians to pay some \$10,000 to start in practice.

The voluntary hospital system has been heading for bankruptcy for several years—a fate which increased gifts and hospitalization insurance have only postponed.

As a result of the war, some of these hospitals began, for the first time in history, to bank money. They were paid by the state to keep the beds empty for casualties. The government leased these beds at anything from two and a half guineas to seven guineas a week (about \$8 to \$25). The hospitals were then able to lease emergency hospitals, built by the state, with the help of the bed rent from the state. This paradoxical device maintained the façade of the voluntary system. And since the war began, hospitals have been among the main targets of the Nazi air raiders, and an essential part of the postwar replanning will have to deal with their rebuilding.

Private practice has been hard hit. Large numbers of doctors have been recruited for the forces and others taken into the government's hospital scheme. Expansion of industrial practice and special shelter service have taken others, and evacuations and the creation of "defense areas" have caused widespread dislocations. It has also brought some steps toward reorganization and numerous proposals for reconstruction after the war. A "regional plan" for hospitals to include both voluntary and government operated hospitals has been developed, and there

seems to be a trend toward state medicine with salaried physicians as part of an integrated system.

Manifestly the old order in medicine is finished.

One thing is certain: We shall have the right to demand after this not the sickness service, which is all we have got at the moment, but a health service, embracing the whole population, irrespective of income, and providing medical care from birth to death, not as a purchasable commodity, but as an inalienable right. That service would conceive health as a biological trinity—protective medicine, which includes nutrition and environment (positive health); preventive medicine, which is the public health services, our pickets against disease; and curative medicine, including early diagnosis and highly skilled treatment, with all the resources of modern medical science and practice.

COMPULSORY SICKNESS INSURANCE IN CALIFORNIA

The proposal to secure signatures for a referendum for compulsory sickness insurance in California received a setback when the members of the influential Commonwealth Club voted opposition to any such system of sickness insurance.

To the question "Do you favor the establishment by government of a system of compulsory sickness insurance (health insurance)?" eight hundred and seventy-one members voted No and four hundred and ninety-one members voted Yes.

Ballots on this question were mailed to all of the Club's four thousand four hundred members following a study by the Public Health Section and publication of pro and con reports on the issue.

TUBERCULOSIS MORTALITY

In 1900 there were 200 deaths per hundred thousand annually from tuberculosis in the United States, according to the statisticians of the Metropolitan Life Insurance Company. In 1921 that rate had been halved and in 1940 the reports now available indicate that it will be more than halved again, since it will be a little less than 45 per hundred thousand. However, the rate of decrease seems to be slowing up. The year 1936 even showed a slight increase. Contrary to expectations, the rate of decline was a little faster during the greatest depression years than in some of the subsequent years. In 1940, twelve states had death rates from tuberculosis below 30 per hundred thousand and six of 20 or less per hundred thousand.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Supervisor of Student Health Service.—Dr. William J. Norris has been appointed university physician and will take general charge of the student health service on the Los Angeles campus of the University of California. He will not replace Dr. Donald S. MacKinnon, physician for men, or Dr. Lillian R. Titcomb, physician for women, according to the University *Clip Sheet*. Dr. Norris was formerly connected with the Los Angeles campus, serving as physician for men from 1921 to 1932. He graduated at Columbia University College of Physicians and Surgeons, New York, in 1918. The *Clip Sheet* stated that the appointment of Dr. Norris anticipates the building of a \$1,000,000 Student Health Center and Hospital on the Los Angeles campus.

Dr. Housman Resentenced to San Quentin.—Superior Judge Lile T. Jacks sentenced Dr. Nathan S. Housman, San Francisco, on October 24, to serve from one to fourteen years in San Quentin, on conviction of perjury and offering and preparing false evidence in connection with an earlier trial for failure to keep proper records of narcotic prescriptions. This judgment was a resentence, confirming an earlier sentence on three counts to run concurrently. Dr. Housman was first sentenced on June 13, 1940 after the court had denied motion for a new trial. He had been indicted Nov. 1, 1939 on six counts: two of perjury, two of preparing false evidence and two of offering false evidence. He appealed to the state appellate court and then the state supreme court. His appeal to the U. S. Supreme Court to review his case failed.

COLORADO

Place of Annual Session.—The Colorado State Medical Society has announced that its seventy-second annual session will be held in Colorado Springs, Sept. 23-26, 1942.

Industrial Hygiene Division.—The Colorado industrial hygiene unit, formerly a section of the division of sanitary engineering, has been established as a separate division of the state board of health, it was announced in September. Mr. R. J. Owens is director of the new division.

The Friedman Lectures.—The William S. Friedman Lectures, sponsored by the National Jewish Hospital, Denver, in cooperation with the Denver County Medical Society and the University of Colorado School of Medicine, Denver, were delivered in November by Drs. Jesse G. M. Bullowa, clinical professor of medicine, New York University College of Medicine, New York, and Leo Eloesser, clinical professor of surgery, Stanford University School of Medicine, San Francisco. Dr. Bullowa spoke on "Chemotherapy in the Pneumonias and the Immunity Reactions" and Dr. Eloesser on "Causes of Cavitation in Pulmonary Tuberculosis." At a special meeting of the Medical Society of the City and County of Denver on November 18 Dr. Eloesser discussed "Compound Fractures in War Time" and Dr. Bullowa "Pneumonias in the Infectious Diseases of Childhood." Both men conducted clinics. Local physicians also participated in the program.

ILLINOIS

State-Subsidized Tumor Diagnostic Service.—The second state-subsidized tumor diagnostic service has been established at the Methodist Hospital of Central Illinois, Peoria, with the approval of the Peoria County Medical Society. The first was begun at the Memorial Hospital of Springfield on October 1. Plans for a tissue diagnostic service at the Marshall Browning Hospital, Du Quoin, have been approved by the Perry County Medical Society and it is expected that this unit will soon be in operation. Although the program for this diagnostic service is administered by Dr. Raymond V. Brokaw, chief of the division of cancer control of the state department of health with headquarters in Springfield, the actual management of the services will be the responsibility of the selected hospitals which are chosen by the local medical society. These tumor diagnostic services are designed to provide for the gen-

eral practitioner a competent consultation service without cost for his suspected cancer cases. The facilities will be available to every physician for the reference of his case for diagnosis and recommendation as to treatment, the patient being returned to the physician for further action. No treatment is to be rendered by this service in any case. The tissue diagnostic service provided for by the 1939 legislature was inaugurated in September 1940 as a function of the division of laboratories of the health department at 1800 West Fillmore Street, Chicago. The act creating the division of cancer control provided for an advisory board of seven members to be appointed by the governor. To make these appointments "the governor shall invite nominations from recognized medical organizations of this state," and no less than four members should be recognized authorities in the cancer field, and at least four should be physicians. At present the board consists of Drs. David J. Davis, Chicago, chairman; William M. Cooley, Peoria; Fauntleroy Flinn, Decatur; Roswell T. Pettit, Ottawa; James S. Templeton, Pinckneyville; John A. Wolfer, Chicago, and Edwin F. Hirsch, Chicago, secretary.

CHICAGO

Symposium on Old Age.—The Chicago Medical Society devoted its December 10 meeting to a symposium on old age. Speakers were Edmund V. Cowdry, Ph.D., St. Louis, on "The Problem of Aging"; Dr. Wilber E. Post, "Medical Management of the Aging Patient"; Dr. Lester R. Dragstedt, "The Aged Patient as a Surgical Risk," and Dr. Francis J. Gerty, "Psychologic Problems in the Aging Patient."

Annual Surgical Prize.—The Chicago Surgical Society announces that competition for the 1942 annual prize is now open to young men devoting themselves to surgery in Cook County and who are not members of the society. A prize of \$250 will be awarded for the most meritorious original investigation in one or both of the fields of experimental and clinical surgery. The paper submitted should be of original work which has not been printed or presented previously. The manuscript should bear no identification marks of author, hospital or institution but should be accompanied by a sealed envelop bearing on its outside the title of the paper and containing within the name and address of the author. No award will be made if no paper submitted is deemed worthy. Manuscripts should be sent to the secretary of the Chicago Surgical Society, 54 East Erie Street, not later than March 1.

INDIANA

Personal.—Dr. Charles P. Anderson, assistant superintendent of the health department in Durham, N. C., has been appointed director of the School Medical Service of Gary. Dr. Robert A. Nason, Garrett, has been appointed coroner of DeKalb County, filling the unexpired term of the late John R. Clark, Auburn. Dr. Harley F. Flannigan, Lagrange, has been named health commissioner of Lagrange County, succeeding Dr. Frank Morse Nichols, Topeka, resigned. Dr. Nichols and his family are moving to Warsaw.

District Meeting.—The Third District Medical Society was addressed in French Lick, November 5. Dr. Carl P. Huber, Indianapolis, opened the session with a discussion of "Normal Delivery, Episiotomy, Forceps and Cesarean Section." Other speakers were Drs. Minor W. Miller, Evansville, on syphilis; Arthur F. Weyerbacher, Indianapolis, gonorrhea; R. Hayes Davis, Louisville, pneumonia; Russell A. Sage, Indianapolis, ear infections; Wendell D. Little, Indianapolis; Louis H. Segar, Indianapolis, rheumatic fever; George J. Garceau, Indianapolis, fractures; Louis Wallace Frank, Louisville, peptic ulcer, and James O. Ritchey, Indianapolis, the after dinner speaker, "Endocrine Disorders."

KANSAS

Rehabilitation Program Begun.—The Kansas State Board of Health, Topeka, is sponsoring a program of rehabilitation of selective service registrants who have been rejected for military service by reason of physical disabilities. Statistical information on registrants who are afflicted with diseases of the lungs and venereal disease is now being assembled, the program to be extended into other fields when facilities permit.

Society News.—The Wyandotte County Medical Society will be addressed, December 16, at its annual meeting by Dr. James W. May on "Common Tumors of the Eye." Dr. Tom R. Hamilton spoke on "Blood Cultures in Clinical Pathology" at the society's meeting December 2 and Dr. Ward W. Summerville, "The Friedman Test." All are from Kansas City.

MINNESOTA

Society News.—Karl F. Meyer, Ph.D., of the George Williams Hooper Foundation for Medical Research, University of California, San Francisco, will address the Minnesota Pathological Society in Minneapolis, December 16, on "The Animal Kingdom, a Reservoir of Infection." The society was addressed, November 18, by Melvin H. Knisely, Ph.D., Chicago, on "Effects of Plasmodium Malariae on the Blood Vascular System."

Medals Awarded.—Dr. Edward H. Juers, Red Wing, recently received the annual medal of the Southern Minnesota Medical Association for his paper on epiloitis. The medal is given to the author of the paper considered best on the program of the association's annual meeting. The medal for a case history presented on the annual program went to Dr. Peter E. Hermanson, Hendricks, whose report dealt with a case of pregnancy occurring outside the uterus.

NEVADA

District Meeting of Indian Service.—The U. S. Indian Service conducted a district medical meeting for California, Nevada and Utah in Reno, November 12-13. Included among the speakers were:

- Dr. Ralph B. Snively, San Francisco, Indian Health and National Defense.
- Dr. Fred T. Foard, San Francisco, Defense Created Public Health Needs in the Western States.
- Dr. Hubert V. Hailman, Salt Lake City, Trachoma, the Enigma.
- Dr. Horace De-Lien, San Francisco, Case Finding in Tuberculosis.
- Dr. Michel Pijon, Owyhee, A Study of Vitamin Deficiencies at Western Shoshone.
- Dr. Roland W. Stahl, Reno, Role of Histamine in Allergy.
- Mr. Don C. Foster, superintendent, Carson Indian Agency, Stewart, History of Development of Indian Service in Nevada.
- Mr. W. W. White, sanitary engineer, Nevada State Health Department, Reno, Sanitary Engineering Aspects of Communicable Disease Control.

NEW JERSEY

Society News.—Dr. Irving S. Wright, New York, will discuss "Peripheral Vascular Diseases" before the Bergen County Medical Society, Hackensack, December 9.—The Passaic County Medical Society devoted its meeting in Paterson on November 13 to a discussion of "State Medicine—Its Trends." The speakers were Drs. Thomas K. Lewis, Camden, and Leroy A. Wilkes, Trenton, president and executive officer respectively of the Medical Society of New Jersey.—Dr. Aaron H. Neffson, New York, addressed the Monmouth County Medical Society in Matawan, November 26, on "Management of Acute Laryngotracheobronchitis."—The Camden County Medical Society was addressed in Camden, December 2, on "Surgical Therapy in Lesions of the Large Bowel."

NEW YORK

Rochester Academy Rededicates Museum.—The Rochester Academy of Medicine, Rochester, rededicated its medical museum to Dr. John R. Williams, chairman of the museum commission, November 16. A reception to guests opened the program and speakers included Dr. William J. Merle Scott, president of the academy; Dr. George H. Whipple, professor of pathology and dean, University of Rochester School of Medicine and Dentistry; Dr. Walter B. Cannon, George Higginson professor of physiology and head of the department, Harvard Medical School, Boston, and Dr. Williams. The museum and auditorium are located in a new wing adjoining the academy's home, which was the gift in 1938 of the daughters of E. P. Lyon in memory of their parents. A feature of the medical museum is a memorial frieze in which is recognized the fundamental contributions made by twenty-four North American scientists in the past hundred and fifty years. Those honored in the frieze are:

- Dr. Benjamin Rush, Philadelphia.
- Dr. William Beaumont, St. Louis.
- Dr. Crawford W. Long, Athens, Ga.
- Dr. William T. G. Morton, New York.
- Dr. Oliver Wendell Holmes, Cambridge, Mass.
- Dr. Ephraim McDowell, Danville, Ky.
- Dr. Silas Weir Mitchell, Philadelphia.
- Dr. Edward L. Trudeau, Saranac Lake, N. Y.
- Dr. Theobald Smith, Princeton, N. J.
- Dr. Howard T. Ricketts, Chicago.
- Dr. Hans Zinsser, Boston.
- Dr. Harvey Cushing, New Haven, Conn.
- Lafayette B. Mendel, LL.D., New Haven, Conn.
- Elmer V. McCollum, Sc.D., Baltimore.
- Dr. William C. Gorgas, Washington, D. C.
- Dr. Walter Reed, Washington, D. C.
- Dr. Abraham Jacobi, New York.
- Dr. William Osler, Oxford, England.
- Dr. Walter B. Cannon, Boston.
- Dr. James B. Herrick, Chicago.
- Dr. Frederick G. Banting, Toronto.
- Dr. Charles H. Best, Toronto.
- Dr. George R. Minot, Boston.
- Dr. Whipple.

Another feature is a mural in which is portrayed the contributions of medicine to modern civilization. There are in the

museum twenty-three glass cases of priceless memorabilia. Special guests at the dedication included relatives of the honored scientists. In 1936 the medical museum of the Rochester Academy of Medicine was organized as a division of the Rochester Museum of Arts and Sciences.

New York City

Annual Fraternity Lecture.—The Tau chapter of Nu Sigma Nu will offer its annual open lecture, December 15, in the auditorium of Cornell University Medical College. Dr. George J. Heuer, professor of surgery at Cornell will deliver the lecture on "William S. Halsted."

Committee for Russian War Relief.—A Medical Center Committee to Aid Russian War Relief was recently organized with Dr. Tracy J. Putnam, director of the Neurological Institute of New York, as chairman; Dr. Alwin M. Pappenheimer, professor of pathology, Columbia University College of Physicians and Surgeons, treasurer, and Elvin A. Kabat, Ph.D., of the Neurological Institute, secretary. Members of the staffs of the various units forming the Medical Center at 168th Street and Broadway are included in the membership of the committee, which has for its purpose the collection of medical supplies and instruments for the relief of the Russian people.

Ophthalmologists Honored.—Dr. John E. Weeks, professor of ophthalmology emeritus, New York University College of Medicine, was guest of honor at a dinner, October 6, attended by eighty friends and students. Dr. Daniel B. Kirby, professor of ophthalmology at the university, was toastmaster. At the dinner it was announced that the Eye Surgery Fund, a local corporation, had been dedicated to the late Dr. Webb W. Weeks, professor of ophthalmology. The fund is now directed by a medical board consisting of certain members of the faculty of the department of ophthalmology of New York University College of Medicine and of the staff of the department of ophthalmology of Bellevue Hospital. It aims to promote and aid research in surgery of the human eye, disseminate knowledge in this field among physicians and particularly to perform such work as may aid the indigent in need of eye surgery or medical care. While the scope of the fund is now local in character, it is hoped to extend it to a national basis.

NORTH CAROLINA

Dr. Royster Observes Seventieth Birthday.—The Raleigh Academy of Medicine was entertained at a dinner November 19, by Dr. Hubert A. Royster to celebrate his seventieth birthday. Dr. Royster is a descendant of one of the founders of the academy, Dr. Wisconsin I. Royster. The speakers included Drs. Chauncey L. Royster, Raleigh, nephew of the host, on "Early Diagnosis of Shock." Two sons, Dr. Henry P., Philadelphia, and Hubert A. Jr., Bryn Mawr, Pa., spoke on "Nutrition in Surgical Patients" and "Resuscitation of the Newborn," respectively. Dr. Royster was born in Raleigh on Nov. 19, 1871. He graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1894. He was dean and professor of gynecology at the University of North Carolina Medical Department, Raleigh, from 1902 to 1910 and since 1935 has been professor of surgery at Wake Forest College, now known as the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem. He was president of the Raleigh Academy of Medicine in 1905, of the Tri-State Medical Association in 1906 and the North Carolina State Medical Society in 1921-1922. Dr. Royster served as chairman of the Section on Surgery, General and Abdominal, of the American Medical Association in 1931-1932.

OHIO

Society News.—Dr. Gordon F. McKim, Cincinnati, addressed the Montgomery County Medical Society in Dayton recently on "Infections of Upper Urinary Tract."—Dr. Claude S. Beck, Cleveland, discussed "Heart Disease Treated by Operation" before the Mahoning County Medical Society, November 18.

Henry Freiberg Memorial.—The Journal of Medicine for November was dedicated to the memory of Dr. Henry B. Freiberg, who at the time of his death in January was assistant professor of clinical surgery (urology) at the University of Cincinnati College of Medicine. Dr. Freiberg was at one time secretary of the Cincinnati Academy of Medicine which, with other societies, publishes its proceedings in the Journal of Medicine.

Commission for the Blind.—Dr. Albert D. Frost, Columbus, has been elected president of the Ohio Commission for the Blind. Other members are Walter Schmitt, Cincinnati; Henry J. Robison, chief of the division of social administra-

tion, state department of public welfare, and Byron P. Redman, Columbus; Mrs. J. D. Johnson, Celina, and W. G. Scarborough, superintendent of the Ohio State School for the Blind, Columbus.

PENNSYLVANIA

Academy of Physical Medicine.—The Pennsylvania Physical Therapy Association has changed its name to the Pennsylvania Academy of Physical Medicine, according to an announcement from Dr. Alfred J. M. Treacy, Philadelphia, secretary. At its meeting, November 21, the group was addressed by Drs. William H. Schmidt, Philadelphia, on "Treatment of Peripheral Vascular Diseases"; Albert A. Martucci, Philadelphia, "Treatment of Anterior Poliomyelitis," and Oscar T. Wood Jr., Philadelphia, "Treatment of Painful Conditions of the Shoulder."

Philadelphia

British Psychiatrist Gives Weir Mitchell Oration.—Dr. Robert D. Gillespie, London, chief psychiatrist of the British Royal Air Force, delivered the ninth Weir Mitchell Oration of the College of Physicians of Philadelphia, November 30. His topic was "Psychoneuroses in Peace and War, and the Future of Human Relationships."

Pittsburgh

Annual Scientific Day.—The annual "scientific day" of the Montefiore Hospital Association of Western Pennsylvania was held in Pittsburgh, November 15. The program included two clinical sessions and an address by Dr. Ira I. Kaplan, New York, entitled "What Radiation Can Offer in Medicine and Surgery."

The Renziehausen Memorial Lecture.—Dr. Henry Rawle Geyelin, assistant clinical professor of medicine, Columbia University College of Physicians and Surgeons, New York, delivered the sixth Renziehausen Memorial Lecture at the meeting of the Allegheny County Medical Society, November 18. His subject was "Clinical Aspects of Diabetes Mellitus."

Society News.—Dr. Meredith F. Campbell, New York, discussed "Urinary Tract Obstructions in Infancy and Children" before the Pittsburgh Urological Association, November 10, in cooperation with the Pittsburgh Pediatric Society. The Pittsburgh Academy of Medicine devoted its meeting, November 11, to a panel discussion of sulfonamide therapy with the following speakers: Drs. Robert R. Clark, general practice; James M. Strang, internal medicine; Harold G. Kuehner, surgery; Howard H. Permar, pathology; Adelbert Boyd Miller Jr., otolaryngology; James J. Lee, urology, and Theodore O. Elterich, pediatrics. Among others, Dr. Julian M. Rogoff addressed the Pittsburgh Surgical Society, November 14, on "Surgical Aspects of Adrenal Cortex."

RHODE ISLAND

Personal.—Dr. Peter F. Harrington, Providence, has been appointed director of a new division of tuberculosis control in the Providence health department.

Sectional Meeting of College of Physicians.—A New England sectional meeting of the American College of Physicians will be held at Providence, January 14. A tentative announcement lists clinical sessions at the Peter's House at Rhode Island Hospital, under the supervision of Dr. Charles F. Gormly, and scientific discussions at the auditorium of the Rhode Island Medical Library. A dinner at the Squantum Club will conclude the day's program.

SOUTH CAROLINA

Conference on Student Health.—The second annual South Carolina Conference on Student Health, sponsored by the South Carolina Tuberculosis Committee and the National Student Health Association, was held in Orangeburg, November 28-29. The program included a panel discussion on "Present Status of Health Programs in Our Colleges" and committee meetings devoted to "Control of Tuberculosis and Venereal Diseases in Colleges" and "What Shall Health Instruction Include?" The speakers included Dr. Paul B. Cornely, associate professor of preventive medicine and public health, Howard University School of Medicine, Washington, D. C., on "Implications of Draft Rejections to College Health Programs." Dr. Cornely was guest consultant and adviser during all professional sessions of the conference.

VIRGINIA

Postgraduate Clinic.—The twenty-eighth postgraduate clinic of the University of Virginia Department of Medicine and the department of clinical and medical education of the

Medical Society of Virginia was held in Charlottesville, November 14-15. The program consisted of a symposium on gastroenterology and speakers included:

Dr. Porter P. Vinson, Richmond, Va., Diseases of the Esophagus.
Dr. Julian M. Ruffin, Durham, N. C., Present Status of Gastroscopy.
Dr. Chester M. Jones, Boston, Clinical Significance of "Gastritis."
Dr. Thomas T. Mackie, New York, Deficiency States and the Gastrointestinal Tract.
Dr. Warren T. Vaughan, Richmond, Gastrointestinal Manifestations of Allergy.
Dr. Thomas Grier Miller, Philadelphia, Intestinal Intubation.
Dr. William Osler Abbott, Philadelphia, Drugs and the Gastrointestinal Tract.

WASHINGTON

Changes in Health Officers.—Dr. Russell H. Wilson, Bremerton, has been appointed in charge of the Kitsap County health department, succeeding Dr. Harald M. Graning, who was assigned to the Plague Laboratory of the U. S. Public Health Service at San Francisco. Dr. Enil E. Palmquist, Colfax, health officer of Whitman County, has been granted six months' leave of absence to study health administration at the University of Michigan, Ann Arbor. During his absence Dr. Philip J. Holabach, Colfax, will be health officer. Dr. Theodore G. Lathrop, White Salmon, has been appointed acting health officer of Klickitat County.

WYOMING

New Head of Venereal Disease Program.—Dr. Nephi H. Savage, director of the division of epidemiology of the Wyoming State Department of Public Health, Cheyenne, has taken over direction of venereal disease problems in the state, according to *Western Public Health*. Private practitioners will be offered a personal consultation service, and a fourth free venereal disease clinic will be opened soon at Laramie, it was announced.

HAWAII

Federal Grant for Hospital Addition.—Queen's Hospital, Honolulu, has been allowed a grant of \$250,000 from the Federal Works Agency, Washington, D. C., to finance the construction of a one hundred bed wing. The hospital will provide the funds for furnishings and equipment. An appropriation has also been given to the hospital to increase the school of nursing by twenty-five students, bringing the student roll up to one hundred.

GENERAL

Impostor Claims Relationship to Dr. Moorman.—Dr. Lewis J. Moorman, Oklahoma City, writes that a young woman has been traveling about the country calling on physicians and representing herself either as a patient or as a relative of his. The woman then presents a fraudulent check to pay her bill, getting the remainder of the check in cash. In many instances the woman has used the name Marianne Hunt. The name of Miriam Brown has also been used. Dr. Moorman, in disclaiming any knowledge or relationship, urges physicians to be on the watch for this woman.

Residency in Anesthesiology.—Applications are now being received for appointment of two residents in anesthesiology at the Cook County Hospital, Chicago, in 1942. The appointments will be for three years, with salary and full maintenance, and the training provided will lead to certification by the American Board of Anesthesiology. The residencies are open to recent graduates of approved internships. Dr. Hugh O. Brown, formerly first assistant in the section on anesthesia, blood transfusion and intravenous therapy of the Mayo Clinic, Rochester, Minn., is director of the department of anesthesia at Cook County Hospital.

Russian Government Asks for Books.—An urgent request from the Soviet government for American medical books to supplement the Central Medical Library was received on November 19 at the offices of Russian War Relief, Inc., 535 Fifth Avenue, New York. The list, comprising almost a hundred titles, includes books on brain, spine and neurologic surgery. According to the announcement the Russian government offered to exchange important recent Soviet literature on medicine for some of the more urgently needed volumes in the listing, such as Albee's "Bone Graft Surgery in Disease, Injury and Deformity," Brock's "Injuries of the Skull, Brain and Spinal Cord: Neuropsychiatric, Surgical and Medicolegal" and Hertzler's "Surgical Pathology of Diseases of the Mouth and Jaws."

Conference on Tuberculosis Establishes New Award.—The Mississippi Valley Conference on Tuberculosis at its recent meeting in Columbus, Ohio, presented the first Hoyt E. Dear-

holt Medal to Robert G. Paterson, Ph.D., Columbus, executive secretary of the Ohio Public Health Association. The medal was established last year as a tribute to the late Dr. Dearholt's devotion, service and leadership in tuberculosis work, particularly in the formation of the Mississippi Valley Conference. Dr. Dearholt was for many years executive secretary of the Wisconsin Anti-Tuberculosis Association.

Annual Forum on Allergy.—The fourth Annual Forum on Allergy will be held at the Hotel Statler, Detroit, January 10-11. On Friday preceding the Forum there will be a conducted trip to the allergy clinic of the University of Michigan, Ann Arbor, where the program will be presented by Dr. John M. Sheldon and his staff. Saturday will be given over to a series of study groups at which the speakers will include:

Dr. Karl D. Figley, Toledo, Ohio, Perennial Allergic Coryza.
Dr. Franz L. Blumenthal, Detroit, Contact Dermatitis.
Dr. Theodore L. Squier, Milwaukee, Food Allergy.
Dr. French K. Hansel, St. Louis, Tonsillectomy, Sinus Surgery, and Local Treatment in Nasal Allergy.
Dr. Howard J. Lee, Oshkosh, Wis., Gastrointestinal Allergy, Cyclic Vomiting, and Beginning Migraine.
Dr. Leon Unger, Chicago, Allergic Conjunctivitis.

Saturday evening Dr. Benjamin S. Kline, Cleveland, will discuss "Observations on the Pathology of Allergy" and Dr. Benjamin C. Houghton, Columbus, will show a motion picture on "The Reaction of Sensitized Cells Growing in Vitro to the Appropriate Antigen." Sunday morning will be devoted to symposiums on drug allergy, hay fever and food allergy. At the annual dinner at noon on Sunday the second award of the Forum's Gold Medal for "outstanding contributions to clinical allergy" will be made by Dr. William W. Duke, Kansas City, Mo. Dr. Milton B. Cohen, Cleveland, will make the presentation. Dr. Duke will deliver the annual lecture on "Beginning of Clinical Allergy in the United States." A special lecture will be given by Dr. Harry L. Alexander, professor of clinical medicine and acting head of the department, Washington University School of Medicine, St. Louis, on "Considerations of the Present Status of Clinical Allergy." The session will be concluded with a program entitled "Information on Allergy, Please," aimed to answer any questions not handled in the general program. Features of the general program will include educational exhibits and "The Picture Theater."

Symposium on Relapsing Fever.—Section N of the American Association for the Advancement of Science will devote its meeting, December 30, in the Medical Arts Building in Dallas to consideration of the "Contributions to the Study of Relapsing Fever in the Americas." Dr. Walter H. Mour-sund, Dallas, will give the historical introduction, other speakers will include:

Dr. Harry E. Wright, Texas State Department of Health, Austin, Texas, Present Distribution, Texas.
Wilton M. Fisher, M.S., instructor in bacteriology and parasitology, Baylor University College of Medicine, Dallas, Tex., Present Distribution in Oklahoma.
M. Dorothy Beck, bureau of epidemiology, state department of public health, San Francisco, Present Distribution, California.
Dr. Herbert C. Clark, director, Gorgas Memorial Laboratory, Panama, R. P., Present Distribution, Panama.
Herbert C. Johnstone, Ph.D., assistant professor of bacteriology, University of California Medical School, San Francisco, Etiology—Taxonomy.
Gordon E. Davis, Sc.D., bacteriologist, Rocky Mountain Laboratory, U. S. Public Health Service, Hamilton, Mont., Species Unity or Plurality of the Spirochete, Tick Vectors and Life Cycles of Ticks.
Malcolm H. Soule, LL.D., professor of bacteriology, University of Michigan Medical School, Ann Arbor, Mich., Cultivation of Spirochetes.
Robert A. Cooley, Sc.D., Rocky Mountain Laboratory, U. S. Public Health Service, at Hamilton, Determination of Ornithodoros Species.
Dr. Edward Francis, National Institute of Health, U. S. Public Health Service, Washington, D. C., Longevity of Fastening Ornithodoros Tunicata.
Charles M. Wheeler, Ph.D., Hooper Foundation, University of California Medical School, San Francisco, The Distribution of the Spirochetes within the Body of the Vector.
Dr. Harlin L. Wynns, state department of public health, San Francisco, Epidemiology.
Dr. George R. Magee, Yerington, Nevada, Symptomatology, Clinical Diagnosis and Therapy.
Dr. David H. Lawrence and J. L. Terrell, Austin State School, Austin, Texas, Symptomatology of Relapsing Fever Superimposed on Neurosyphilis.
Dr. Sidney W. Bohls and Vernal Irons, Sc.D., Texas State Board of Health, Austin, Laboratory Diagnosis.
Vernon T. Schulhardt, M.A., associate professor of biology, University of Texas at Austin, Serology.
Dr. Hardy A. Kemp, dean, Ohio State University College of Medicine, Columbus, Dr. Fisher and Howard L. Evans, Dallas, Texas, Pathology and Immunity.
Dr. Bohls, Public Health Aspects.

The meeting of the American Association for the Advancement of Science will open in Dallas, December 29, to continue through January 3.

Government Services

First Aid Training by Bureau of Mines

The U. S. Bureau of Mines, Washington, D. C., during the last fiscal year gave first aid training to nearly 100,000 persons, raising the total number of persons who have received first aid certificates from the bureau of mines to more than 1,375,000. The bureau has also given instruction in the use of gas masks and in methods of handling explosions and fires in mines to about 75,000 persons. Nevertheless, in coal mines during the year there were seven major disasters with a total of 155 deaths, as compared with three major disasters and 206 deaths for the fiscal year 1940. To help reduce injuries in coal mines, the Congress of the United States passed on May 7 the Federal Mine Inspection Act, which empowers the Bureau of Mines to make inspections and investigations in coal mines. A corps of mine inspectors will be selected and laboratory facilities expanded to handle the work of investigating health and safety in coal mines.

New Naval Medical Center

The new U. S. Naval Medical Center at Bethesda, Md., which is now ready for occupancy, has been completed at a cost of \$7,000,000. It is expected that moving from present facilities in Washington, D. C., will take place after January 1. The center includes the Naval Hospital, Naval Medical School, Naval Dispensary and Naval Dental School, situated on a 247 acre reservation. The tower of the administration building, which is set on a hill facing the Rockville Pike, will be devoted to wards and individual sickrooms, is twenty stories high and rises to a height of 270 feet above the Rockville Pike. The

The new U. S. Naval Medical Center.

fourth floor of the administration building extends the full length between the wings and will house principally the x-ray department and an auxiliary surgical service. The Medical Center consists of a central group of buildings, which includes administration offices, laboratories, classrooms, a surgical pavilion, two ward buildings, ship's service, commissary and recreation facilities, including a movie theater seating six hundred. The hospital corps quarters accommodate two hundred and eighty-five men, and the nurses' quarters accommodate seventy nurses. The hospital, which has a capacity of four hundred and fifty beds, in addition to an outpatient department, will utilize the clinical laboratories of the medical school. The Naval Medical School will conduct post graduate courses in phases of medicine peculiar to naval service, such as field hygiene related to service with the marines, submarine hygiene and physiologic problems related to deep sea diving, aviation medicine and tropical diseases. The training courses conducted for hospital corpsmen of the navy will include those for x-ray, chemistry, pharmacy, clinical laboratory, epidemiologic and blood plasma technicians. The Naval Medical Center will have a medical library large enough to accommodate seventy thousand volumes and a "crew's" library for the general use and recreation of patients and staff. Special facilities have been provided for research. Special attention will be given to epidemiology and to the effects of increased and decreased air pressure having a relation to the depth to which divers may descend and the heights to which aviators may climb.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 25, 1941.

National Health Good After Two Years of War

In previous letters the satisfactory condition of national health, which has actually improved under war conditions, was stated. These reports are now confirmed by Sir Wilson Jameson, chief medical officer of the Ministry of Health, who says that at the close of the second summer of war we have every reason to be thankful for the health of the country and that there is no reason to be pessimistic about the third winter, but that every conceivable care should be exercised and local authorities and the medical profession must remain alert. Most of the infectious diseases have declined steadily. Scarlet fever and diphtheria are less prevalent than a year ago. In the first week of September the number of cases of measles was only one sixth of the number in the corresponding week of last year. Cerebrospinal fever touched its lowest level for many months in the last week of August. There are still over 3,000 cases of whooping cough a week, but not long ago the number was well over 4,000. Enteric fever, notably paratyphoid, is more prevalent than in 1940. The ministry is pushing forward with diphtheria immunization. The percentage of children immunized in different cities varies from 60 upward and in one city has reached 95. Jameson points out that it costs 15 cents to immunize a child but over \$150 to treat one for diphtheria in a hospital. There has been a rise in deaths from pulmonary tuberculosis, mostly among females of ages between 15 and 25 years. Deaths due to air raids have been least among children of school age, which is due to their evacuation to safer areas in the country. Possibly this also explains the decline of infectious diseases among them.

There is an epidemic of paratyphoid fever in Bristol, where a mobile team of the Harvard Medical Unit is working. Jameson says that if all who handle food would wash their hands before doing so these paratyphoid outbreaks would soon cease. One of the first persons to fall ill of the disease in Bristol was engaged in the preparation of food, and this was more or less responsible for the widespread outbreak. The Harvard team in Bristol consists of a medical officer, two laboratory workers, six hospital nurses and six public health nurses.

Medical Cooperation with Russia

A committee consisting of Lord Dawson, Sir Gowland Hopkins and Prof. J. A. Ryle has been formed to arrange the interchange between the British medical profession and that of the Soviet Union of the latest material on medicine. It is called the Anglo-Soviet Medical Committee. The members hold that such an interchange can be of value at present to members of the profession in both countries and that a large number of British physicians would be willing to cooperate in the work. Those interested and prepared to assist by abstracting English articles and translations of Russian work are invited to write to the committee at the house of the Royal Society of Medicine.

American Hospital in England

In the south of England is an all American complete field hospital with nine wards, a fully equipped kitchen, a pathologic laboratory and accommodation for the medical and nursing staff, consisting entirely of American volunteers. The roofs, floors, walls, every bolt and screw and all the furniture and equipment have been shipped from America as a gift from the

American Red Cross and Harvard University. The hospital is constructed of timber throughout and was delivered on the site in prefabricated sections ready for immediate assembly. It has been put together under the supervision of Mr. Gwyer, an American. It is estimated that, by employing thirty men with a knowledge of this system of construction, a hospital of this size can be assembled and equipped in less than twenty-five weeks. The hospital incorporates a mobile field unit. The director is Dr. John E. Gordon, professor of preventive medicine and epidemiology at Harvard University. The university has also supplied the whole of the medical staff.

Reduction in Civilian Air Raid Casualties

The Ministry of Home Security has published figures showing a great reduction in civilian casualties from air raids since these reached a maximum in September 1940. For August 1941 the figures were 169 killed and 136 injured and detained in hospitals. From Sept. 3, 1939 to July 31, 1940, a period before air raids on this country developed, the civilians killed numbered only 310. Then raids on a large scale began and the number killed increased considerably: in 1940 August 1,085, September 6,955, October 6,335, November 4,751, December 3,829; in 1941 January 1,539, February 793, March 4,298, April 6,068, May 5,394, June 399, July 501. The great decline since May coincides with raids on a much smaller scale, which can be explained by the attack on Russia.

BUDAPEST

(From Our Regular Correspondent)

Oct. 3, 1941.

New Law on Protection of the Magyar Race

On October 10 the new law on the protection of the Magyar race will enter into force. The law forbids marriage between Jews and non-Jews. When Christians marry and four or at least three of their grandparents are Gentiles, according to their best knowledge, no documentary evidence has to be produced at the marriage registry offices. But if only two grandparents are or were Christians, rigorous certification is demanded as to the applicants' descent. In cases of marriage in spite of the new marriage law by misleading statements the law empowers the misled party to take legal steps for the dissolution of the marriage. The law prescribes severe punishment for Jews who have sexual intercourse with native Magyar, non-Jewish woman. Henceforth persons wanting to marry must have a thorough medical examination, must be made by city medical officers of health in towns and cities and district physicians in the country. The examinations are made gratuitously, a certain fee for these being paid by the state.

The Remains of Primitive Men in the Aggtelek Cave

Aggtelek, a stalactitic cave in upper Hungary, attracted the attention of archaeologists about the middle of the nineteenth century when Christian Raisz began to examine its queer formations. In the course of his investigations, in one section of the cave which is cut into halves by the water of Acheron, in the stalactites he hit on a whole series of skeletons placed one above the other. He named this part a mausoleum. In the vicinity of the skeletons he found various kitchen utensils and decorative objects. The forms of the vases pointed to a refined taste, and the coloring and finishing to an elaborate sense of art. Raisz could not explain their presence in the cave except as a result of the Tartar invasion. His assumption was that when Batu Khan's barbarian hordes invaded the country a part of the population sought refuge in the cave. Later scientific excavations refuted Raisz's assumption. In 1876 Professor Nyáry discovered two other caves in the vicinity of the mausoleum. Fragments of tile, human skeletons, the remainders of cave dwelling bears and other animals, lances made from bear bones, spear tips, chisels, amulets, axes and saws made of fish

bones came to light. They disclosed that the cave of Aggtelek had been a human living place beginning from the stone age through the paleolith and neolith and iron age until historical times. The seeds of wheat, lentil, rye, barley and the remainders of fourteen animals corroborate the assumption that the inhabitants of the cave knew agriculture and the breeding of useful animals. Examination of the skeletons revealed that they originated from primitive Magyars and by scientific comparison they could be strictly delineated from skeletons originated from the invading Mongolians and Tartars. Many of the skeletons are on exhibit at the Ethnographical Museum in Budapest.

Tolerance of Young Cats for Chloroform

Katona and Besenyei studied chloroform narcosis on young cats of different ages. They observed that the blood pressure of grown up animals falls at the outset of narcosis, while that of young animals during the course of narcosis does not change much. In young animals periodic fluctuation of blood pressure is frequent in conjunction with partial respiratory paralysis about the end of narcosis. This phenomenon was observed by them also on grown up animals. The pulse rate of adult animals gradually decreases from the beginning of narcosis, while that of young animals decreases only after a transitory rise, and in deep narcosis it rises again. The respiration of adult animals is accelerated during the whole course of the narcosis; young animals breathe rapidly, but in deep narcosis the rate of respiration falls below normal. Partial respiratory paralysis with periodic respiration is of frequent occurrence: this is never observed on adult animals. The cause of death of adult animals from narcosis frequently is syncope. Katona and Besenyei believe that for the purposes of surgical narcosis chloroform is safer in the developing age than in adults but that does not mean it is so toxic as to justify its disuse in cases in which ether is contraindicated.

Formula for Estimation of Increase of Length and Weight of Infants

Dr. Joseph Lukács has compiled formulas with which one can easily calculate normal length and weight data. 1. The normal body weight of an infant is obtained by multiplying the age in months by 600 and adding this sum to its birth weight. If the latter is unknown, an average of 3,300 Gm. is taken. For instance, a 5 months old infant with a birth weight of 3,100 Gm. should weigh $5 \times 600 + 3,100 = 6,100$ Gm. The body weight of children between 1 and 12 years of age is obtained by subtracting 1 from the number of years, multiplying the remainder by 2 and adding 10. For instance, the weight of a child of 9 years is $9 - 1 = 8 \times 2 + 10 = 26$ Kg. These formulas give average figures. The weight of girls is slightly less than that of boys, so that if the formula is applied for girls the value obtained should be taken as optimal, while for boys it is minimal. 2. The normal height of an infant is obtained by multiplying its age in months by 2 and adding 52 to the sum obtained. Thus the length of an 8 months old infant is $8 \times 2 + 52 = 68$ cm. The height of a child of 2 to 4 years is obtained by multiplying the age in years by 10 and adding 60 to the sum. For instance, the normal height of a 3 year old child is $3 \times 10 + 60 = 90$ cm. The height of children between 5 and 14 is reckoned by multiplying the age in years by 5 and adding 80 to the sum. For instance, the height of a child of 6 is $6 \times 5 + 80 = 110$. In regard to the body length, the difference between boys and girls is negligible.

New Institution for Research on Nutrition

The Ministry of Internal Affairs has established a new institute for research in proper feeding. The institute, which is in Budapest, will be opened in the next few days. The building and equipment are modern and will accommodate two hundred country doctors, who will attend courses in the science of feeding. The staff of the institute comprises clinicians, chemical experts, economists and financial experts.

RIO DE JANEIRO

(From Our Regular Correspondent)

Oct. 11, 1941.

Brazilian and American Congress of Surgery

The third Brazilian and American Congress of Surgery, organized by the Brazilian College of Surgeons, will be held November 16-20 at Rio de Janeiro. The official subjects will be "Surgery of Pain," "Burns" and "Amputations from the Functional Point of View." This congress will draw to Rio de Janeiro many important surgeons from North and South America. Among the foreign surgeons will be Prof. Julio Diez of Buenos Aires, Argentina, and Prof. Manuel Riveros of Assuncion, Paraguay, who are official translators for the congress. The president will be Prof. Benedito Montenegro of the University of São Paulo.

Pulmonary Schistosomiasis (Mansoni)

A clinical study of pulmonary schistosomiasis (mansoni) has been made by Dr. João Alves Meira, assistant of the Faculty of Medicine of São Paulo and a specialist on tropical diseases. The 4 cases described show that there is a pulmonary form of schistosomiasis (mansoni). In some cases the diagnosis can be made only by examination of the sputum, by roentgenograms and by a therapeutic test. The pulmonary forms occur especially in patients who have visceral schistosomiasis of advanced degree.

The roentgen evidence of the pulmonary forms alone cannot be accepted, for confirmation by other data, such as the presence of the parasite's eggs in the sputum, is required. Eosinophilia may be transitory, but its presence is important.

The prognosis varies with the clinical form of the disease. The most serious manifestations are those caused by endarteritis complicated by cardiac insufficiency. When pulmonary aspects occur in advanced cases of the disease with a picture of hepatic cirrhosis and splenomegaly, the prognosis is generally grave.

Marriages

KENNETH L. MCGUIRE, Richland, Iowa, to Miss Alta Patricia McDEVITT of Spokane, Wash., in Fairfield, Iowa, October 9.

WILLIAM BEDWELL HARRELL JR., Little Rock, Ark., to Miss Erin Johnson Wallace of Birmingham, Ala., in October.

WALTER JOSEPH DUKSA, Hartford, Conn., to Miss Anna Emily Lennon of Washington, D. C., September 20.

FRANK TRESSLER LINZ to Miss Josephine Gwaltney McGowan, both of Tampa, Fla., October 24.

WILLIAM ALFRED MITCHELL, Newport News, Va., to Miss Ella Walker Hill in Roanoke, November 8.

CORNELIUS P. MURPHY, Alton, Iowa, to Miss Ethel Koelzer of LeMars, at Jordan, Minn., September 15.

WILLIAM PLEAS STONER, Memphis, Tenn., to Miss Edna May Wilson of Guston, Ky., in October.

OLIVE ANGA LUNDGREN, Minneapolis, to Mr. James Gordon Bateman of Great Falls, Mont., June 24.

JOSEPH ARCHER RAVENEL, Charleston, S. C., to Miss Mary Castrinos of New Orleans, November 5.

WILLIAM FRANCIS JACOBS to Miss Mary Margaret Haskins, both of Chicago, in October.

WILLIAM HIGGINSON to Miss Louise W. Sona, both of Nashville, Tenn., in October.

HANNS C. SCHWYZER, St. Paul, to Miss Margaret Nelsen of Minneapolis, October 18.

DERBERT MERENLOOM, Cumberland, Ky., to Miss Nancy Ettin of Harlan in October.

JOHN THOMAS AKIN JR. to Miss Ladye Jane Akin, both of Atlanta, Ga., October 11.

JOSEPH E. PISETSKY, Brooklyn, to Miss Lillian Sax of New York, August 17.

HARRY GIBEL to Miss Pearl Charms, both of Brooklyn, October 19.

Deaths

Kenneth Daniel Blackfan * Boston; Albany (N. Y.) Medical College, 1905; Thomas Morgan Rotch professor of pediatrics at Harvard Medical School and the graduate school; professor of pediatrics at the University of Cincinnati College of Medicine from 1920 to 1923; instructor in pediatrics from 1913 to 1917, associate from 1917 to 1919, and associate professor at Johns Hopkins University School of Medicine, Baltimore, 1919-1920, and lecturer in clinical pediatrics, 1920-1921; assistant at Washington University School of Medicine, St. Louis, 1911-1912; member and past president of the American Pediatric Society; member of the American Academy of Pediatrics, the New England Pediatric Society, Association of American Physicians and the American Society for Clinical Investigation; member of the Harvard Infantile Paralysis Commission; delegate, White House Conference on Child Health and Protection in 1930 and editor of the report in 1932; general secretary of the Fifth International Commission on Nutrition sponsored by the League of Nations in Berlin in 1932; was general secretary of the International Congress of Pediatrics; chairman of the General Advisory Committee on Maternal and Child Welfare under the Social Security Act, from 1935 to 1937; consultant of the Children's Bureau since 1935; member of the Commission on Graduate Medical Education since 1937; honorary member of the Philadelphia Pediatric Society; corresponding member of the Royal Society of Medicine of England (section of the study of disease in children) and the British Pediatric Association; member of the Council on Pharmacy and Chemistry of the American Medical Association from 1934 to 1935; member of the board of directors of the Infants' Hospital; aged 58; died, November 29, at Louisville, Ky., of a malignant tumor of the brain.

Frederick Taylor Lord * Boston; Harvard Medical School, Boston, 1900; assistant in clinical medicine from 1905 to 1909, instructor from 1909 to 1930, clinical professor of medicine from 1930 to 1935 at his alma mater and since 1935 clinical professor of medicine emeritus; past president of the American Association for Thoracic Surgery; formerly vice president of the National Tuberculosis Association; president of the Massachusetts Tuberculosis League; member of the Association of American Physicians; fellow of the American College of Physicians; member of the American Society for Clinical Investigation and the American Clinical and Climatological Association; in 1917 member of the American Red Cross Commission to Serbia; served as visiting physician from 1912 to 1935 and member of the board of consultation since 1935 and in various other capacities at the Massachusetts General Hospital; served as a member of the advisory committees of the state department of public health and the city health department; member of the Boston Council of Social Agencies and chairman of the pneumonia and tuberculosis committees, Boston Health League; author of "Diseases of the Bronchi, Lungs and Pleura" and "Pneumonia"; co-author, with Dr. Roderick Heffron, of "Lobar Pneumonia and Serum Therapy," and "Pneumonia and Serum Therapy" and co-author, with Dr. Elliott S. Robinson and Dr. Heffron, of "Chemotherapy and Serum Therapy of Pneumonia"; aged 66; died, November 4, in the Baker Memorial of the Massachusetts General Hospital of subarachnoid hemorrhage.

James Porter Fiske, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1891; surgeon, Charity Hospital and New York Maternity Hospital, 1891-1892; obstetric surgeon, Church Hospital, and attending surgeon, St. Elizabeth's Hospital, since 1893; orthopedic surgeon, New York Post-Graduate Hospital, from 1895 to 1899; orthopedic surgeon, Roosevelt Hospital, from 1893 to 1901; assistant surgeon, Bellevue Hospital, 1899-1900; orthopedic surgeon, New York Hospital; a founder of the schools for crippled children; past president of the Guild for Crippled Children of the Poor of New York; attending surgeon, Free School for Crippled Children from 1901 to 1913; charter member of the W. H. Davis School for Crippled Children; manager of the New York State Hospital for Crippled and Deformed Children; served during the World War; in 1924 was made a lieutenant colonel in the medical officers reserve corps; aged 74; was killed, October 25, in an automobile accident, near Commerce, Okla.

Menas Sarkas Gregory * New York; Albany (N. Y.) Medical College, New York, 1898; professor of psychiatry, University and Bellevue Hospital Medical College, now known as the New York University College of Medicine, from 1922 to 1936 and since 1936 emeritus professor; formerly professor

of psychiatry, New York Post-Graduate Medical School; member of the American Neurological Association, American Psychiatric Association and the Association for Research in Nervous and Mental Diseases; director of the psychiatric division, Bellevue Hospital, from 1904 to 1934 and since 1936 consultant; served during the World War; aged 69; died, November 2, while playing golf at Tuckahoe, N. Y.

Jack Schluger, Dayton, Ohio; Long Island College of Medicine, Brooklyn, 1936; was commissioned as a first lieutenant, medical corps reserve on June 2, 1936; served as a Civilian Conservation Corps camp surgeon in the Third Corps Area from June 15, 1936 to Jan. 4, 1937, and Oct. 25, 1938 to Sept. 30, 1939; was ordered to extended active duty with the United States Army, effective Aug. 1, 1941 and assigned to Kelly Field, Texas; on the staff of the Veterans Administration Facility, National Military Home; aged 32; was killed, October 14, in an airplane accident ten miles from Greensburg, Pa.

Grant Fletcher Mollring * assistant surgeon, lieutenant, junior grade, United States Navy, Great Lakes, Ill.; University of Nebraska College of Medicine, Omaha, 1936; was appointed assistant surgeon in the medical corps of the United States Navy on Oct. 25, 1940; formerly served with the 10th Provisional Company of the United States Marine Corps at Quantico, Va., and also for a time at one of the new Atlantic bases; at one time surgical assistant at the Parkview Hospital, Rocky Mount, N. C.; aged 27; died, October 27, at the United States Naval Hospital, of acute anterior poliomyelitis.

Cary Robert Pollock, Denver; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; member of the Colorado State Medical Society; was assigned to active duty Oct. 14, 1916 as a first lieutenant medical reserve for a course of instruction at the Army Medical School, Washington, D. C.; commissioned first lieutenant in the regular army medical corps March 28, 1917; promoted to major, March 28, 1918; resigned from the service Jan. 31, 1927; fellow of the American College of Surgeons; on the staff of the Presbyterian Hospital; aged 53; died, October 25.

Seth Selig * New York; Columbia University College of Physicians and Surgeons, New York, 1921; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; medical officer of the city fire department; attended on the Mount Sinai Hospital and the for Chronic Diseases; consulting orthoped hospital, Blythedale Convalescent Home and the New York Jewish Guild for the Blind; aged 44; died, November 2, of coronary sclerosis.

Melville Black * Denver; Bellevue Hospital Medical College, New York, 1889; professor of ophthalmology emeritus at the University of Colorado School of Medicine; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president and secretary of the Colorado State Medical Society; ophthalmologist, St. Luke's Hospital, Children's Hospital and the Colorado General Hospital; aged 75; died, November 12, in St. Joseph's Hospital of bronchopneumonia and pyelonephritis.

Max Talmey, New York; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1894; member of the Medical Society of the State of New York; chief ophthalmologist and aurist at the Yorkville Hospital, now the Beth David Hospital from 1902 to 1908; surgeon at Harlem Eye, Ear and Throat Infirmary from 1905 to 1917; author of a book entitled "The Relativity Theory Simplified"; aged 74; died, November 6, of chronic myocarditis.

George Ambrus * New York; Magyar Királyi Ferencz József Tudományegyetem Orvostudományi Kara, Szeged, Hungary, 1922; formerly assistant professor of pathology at the University of Hungary; director of the New York Physicians and Diagnostic Laboratory; aged 45; died, November 14, in the New York Post Graduate Hospital of carcinoma of the jejunum and abdominal metastasis.

William N. Beggs, Denver; St. Louis Medical College, 1886; member of the Colorado State Medical Society; medical director of Sands Home, Edgewater; on the staff of the Jewish Consumptive Relief Society Sanatorium; aged 79; emeritus member of the staff of the Swedish National Sanatorium, Englewood, Colo., where he died, October 31, of myocarditis and arteriosclerosis.

William Kay Bartlett * Colonel, United States Army, retired, San Francisco; Medico-Chirurgical College of Philadelphia, 1903; entered the medical corps of the United States Army as an assistant surgeon in 1907; served during the World

War; was promoted to the grade of colonel in 1933 and retired in 1935 for disability in line of duty; aged 63; died, November 2.

Thomas Francis Birmingham * Galesburg, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; member of the American Urological Association; president-elect of the Knox County Medical Society; aged 58; on the staffs of the Galesburg Cottage Hospital and St. Mary's Hospital, where he died, November 1, of cirrhosis of the liver.

Guy Payne Sanderson, Vicksburg, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1923; member of the Mississippi State Medical Association and the Southeastern Surgical Congress; served during the World War; served the Vicksburg Hospital in various capacities; aged 43; died, October 30, of acute coronary occlusion.

Willard Richardson Pierce, Milford, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1909; served during the World War; formerly member of the state legislature; member of the state board of health; on the staff of the Milford Memorial Hospital; aged 55; died, October 30, of myocardial degeneration.

Marion Albert Andreen * Chicago; Northwestern University Medical School, Chicago, 1922; associate in otolaryngology at his alma mater; member of the American Board of Otolaryngology; aged 47; died, November 10, at the South Shore Hospital of carcinoma of the gallbladder and cerebral thrombosis.

Chauncey De Witt Beebe * Sparta, Wis.; Northwestern University Medical School, Chicago, 1918; was president of the Seventh District Medical Society; for many years president of the school board of Sparta; on the staff of St. Mary's Hospital; aged 49; died, November 5, of heart disease.

James David McCord, Lynchburg, Tenn.; University of Nashville (Tenn.) Medical Department, 1909; member of the Tennessee State Medical Association; county health officer; medical director and owner of a hospital bearing his name; aged 59; died, October 31, of coronary thrombosis.

Homer Daniel McGill, Clarksburg, Tenn.; Nashville (Tenn.) Medical College, 1878; member of the Tennessee State Medical Association; past president of the Carroll County Medical Society; aged 84; died, October 30, of uremia and prostatic obstruction.

Wallace Henry Carver, Los Angeles; Colorado School of Medicine, Boulder, 1902; served during the World War; aged 66; died, October 5, in the Veterans Administration Facility, West Los Angeles, of bronchopneumonia, arteriosclerosis and nephrosclerosis.

Thomas Hudson Harter, Pasadena, Calif.; University of Pittsburgh School of Medicine, 1914; member of the California Medical Association; served during the World War; chief surgeon, City of Pasadena Emergency Hospital; aged 51; died, October 20.

Emery Wells Goemmel * Rockford, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; aged 60; on the staff of St. Anthony's Hospital, where he died, November 1, of coronary thrombosis.

Lucia Florence Vickery, Boston; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1892; member of the Massachusetts Medical Society; aged 81; died, October 23, of carcinoma of the pancreas.

Benjamin B. Tout, Archie, Mo.; Columbian Medical College, Kansas City, 1901; member of the Missouri State Medical Association; formerly state senator; bank president; at one time postmaster; aged 74; died, October 29, of paralysis agitans.

Adolf M. Silten, New York; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1901; member of the Medical Society of the State of New York; on the staff of the Beth David Hospital; aged 63; died, November 3.

Edward Vincent Murphy, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1914; formerly medical superintendent of the Alexandra Hospital; aged 56; died, October 26, in the Royal Victoria Hospital.

Atherton Perry Mason, Fitchburg, Mass.; Harvard Medical School, Boston, 1882; member of the Massachusetts Medical Society; formerly city bacteriologist; at one time member of the board of health; aged 85; died, October 20.

Herman Henry Moore, Markham, Va.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1908; Detroit College of Medicine, 1909; fellow of the American College of Surgeons; aged 61; died, October 20.

Charles J. Forney, Woodward, Okla.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; member of the Oklahoma State Medical Association; aged 71; died, October 23, in Shattuck of arteriosclerosis.

Blanche Horner Muldoon Bach, Pico, Calif.; Indiana University School of Medicine, Indianapolis, 1910; member of the Medical Society of the State of Pennsylvania; at one time school physician; aged 53; died, September 20.

Elbert Stevenson Dupuy * Beckley, W. Va.; Miami Medical College, Cincinnati, 1901; formerly secretary of the Raleigh County Medical Society; for many years on the staff of the Beckley Hospital; aged 65; died, October 16.

Hugh Boleyn Sprague * Salt Lake City, Utah; Jefferson Medical College of Philadelphia, 1905; served during the World War; formerly police surgeon and assistant city health commissioner; aged 63; died, October 11.

William Rufus King Beck, Jackson, Miss.; Birmingham Medical College, 1914; member of the Mississippi State Medical Association; served during the World War; aged 56; died, November 15, of coronary thrombosis.

William Roderick Dunbar, Truro, N. S., Canada; McGill University Faculty of Medicine, Montreal, Que., 1897; past president of the Nova Scotia Medical Society; aged 71; died, September 12, in New Glasgow.

Walter Oscar Bartlett * Boston; Harvard Medical School, Boston, 1902; aged 62; died, November 5, in the Baker Memorial of the Massachusetts General Hospital of embolism of the right internal carotid artery.

Stonewall Jackson Emory, Navasota, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1893; past president of the Grimes County Medical Society; aged 69; died, October 17.

John W. Bolen, Galax, Va.; Medical College of Virginia, Richmond, 1885; member of the Medical Society of Virginia; aged 80; died, November 2, in St. Albans Sanatorium, Radford, of coronary sclerosis.

Louis Charles Barrette, Sacramento, Calif.; Washington University School of Medicine, St. Louis, 1925; member of the California Medical Association; aged 43; died, November 15, of malignant hypertension.

Margaret Coy-Bryan, Columbus, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1934; member of the Ohio State Medical Association; aged 31; died, October 11, in the White Cross Hospital.

Charles Chessher Foster * Granger, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1893; past president of the Williamson County Medical Society; aged 72; died, October 3.

Frederick Clarence Clarke, Bridgetown, Barbados, British West Indies; McGill University Faculty of Medicine, Montreal, Que., 1908; served during the World War; aged 58; died, September 20.

Chester Cole Ames * Detroit; Detroit College of Medicine and Surgery, 1926; on the staff of the Receiving Hospital, Parkside Hospital and the Trinity Hospital; aged 43; died, November 2.

Frederick Cornelius Macdonald, Boston; Tufts College Medical School, Boston, 1901; member of the Massachusetts Medical Society; aged 65; died, October 27, of coronary thrombosis.

Edward Oliver Bonsteel, Cleveland; Cleveland Homeopathic Medical College, 1903; served during the World War; aged 73; died, November 5, of ruptured aneurysm of the abdominal aorta.

Goldburn H. Wilson, St. Louis; St. Louis College of Physicians and Surgeons, 1889; formerly member of the state legislature; aged 76; died, October 31, of coronary sclerosis.

Emile Roy, Tulsa, Okla.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1901; member of the Oklahoma State Medical Association; aged 78; died, October 13.

Lemuel Martin Roberts, Little Falls, Minn.; Hahnemann Medical College of Philadelphia, 1883; member of the Minnesota State Medical Association; aged 79; died, October 9.

Olaf Magnuson Sattre, Rice Lake, Wis.; Rush Medical College, Chicago, 1888; member of the State Medical Society of Wisconsin; bank president; aged 78; died, October 27.

James H. Guinn, Wilmington, Calif.; Kansas City (Mo.) Medical College, 1886; aged 85; died in July at Los Angeles of arteriosclerosis.

George E. Gwinn, San Antonio, Texas; Barnes Medical College, St. Louis, 1898; died in September.

Correspondence

INTERNATIONAL SOCIETY OF SURGERY

To the Editor:—The opportunity for gathering together a number of the fellows of the International Society of Surgery was presented by their attendance at the recent clinical congress of the American College of Surgeons in Boston, November 3-7.

The minutes of the meeting of certain American, Canadian and South American fellows of the International Society of Surgery at the Harvard Club of Boston, November 6, are as follows (forty-six fellows attended):

A report was given of the inaccessibility of the executive staff of the society following the collapse of France and Belgium. It was pointed out that the president, Dr. Mayer, the secretary general, Dr. Dejardin, and the treasurer, Dr. Lorthioir, were all Belgians and that we had not been able to get in touch with them since the occupation of Belgium.

It was pointed out that the National Committee for the United States and Canada, though it had no desire to continue in office, believed that the International Society of Surgery, the first and for nearly half a century the leading and most authorized exponent of surgical culture and achievement throughout the civilized world, was a necessary part of international medical relations and that temporarily the responsibility for continuing the existence of this society rested on the fellows in the Western Hemisphere.

In conformity with this feeling the committee presented certain resolutions for action by those present in order that the activities of the International Society of Surgery might be continued and fostered during the period of the present war.

The following resolutions were voted on and passed:

1. *Resolved*, That we, Fellows of the International Society of Surgery, here assembled in response to the call of the National Committee for the United States and Canada in Boston, Massachusetts, and coincidentally with the thirty-first Clinical Congress of the American College of Surgeons and in the absence, or lack, of all possible communication with the Executive Bureau at Brussels, do name, elect, and authorize the National Committee of the American Section, consisting of Elliott C. Cutler, M.D., Boston, Massachusetts, Rudolph Matas, M.D., New Orleans, Louisiana, and Eugene H. Pool, M.D., New York, New York, to take appropriate steps to continue their duties and functions until such time as the restoration of peace and order in Europe, and particularly in Belgium, will permit the International Society of Surgery to resume its normal prewar mode of existence.

2. *Resolved*, That the National Committee of the International Society of Surgery in the United States be likewise authorized to enlarge its own committee membership in any way that it may deem necessary to meet the requirements of the Committee and of the Society.

3. *Resolved*, That the National Committee shall be authorized by consultation and correspondence with Western Hemisphere colleagues to perfect further organization.

It was clear that some of the fellows did not feel that the American group had the authority to take over the executive duties of the central organization but felt that it was desirable for all fellows in the Western Hemisphere to join together in continuing the society by an enlargement of the present National Committee for the United States and Canada and by adding to the roster suitable members from all parts of the Western Hemisphere after consultation with the surgical academies and societies now existent. In particular the fellows from Venezuela, Argentina, Brazil and Cuba voiced the opinion that they and their colleagues from Central and South America would be glad to be consulted and to further this activity.

NATIONAL COMMITTEE FOR THE UNITED STATES AND CANADA.

ELLIOTT C. CUTLER, M.D., Boston, Chairman.
RUDOLPH MATAS, M.D., New Orleans.
EUGENE H. POOL, M.D., New York.

POTENCY OF DIGITALIS PREPARATIONS

To the Editor:—In THE JOURNAL, October 11, page 1243, appeared an article calling attention to the increase in potency of the digitalis preparations in the U. S. Pharmacopeia XI, which became official June 1, 1936 (Bland, E. F., and White, Paul D.: The Strength of Digitalis in Clinical Use: A Warning). Unfortunately, not enough publicity was given to the change at the time when it took effect. Further, there has been some controversy as to just what the change was. This communication is written to present the intent of those responsible for the next revision of the U. S. Pharmacopeia.

The change in potency made at the time of the last revision was intended to bring the digitalis preparations of the U. S. Pharmacopeia XI into line with those of countries accepting the League of Nations Standards. In the U. S. Pharmacopeia XI (p. 136) appears the following statement regarding the unit in which the activity of digitalis preparations is to be expressed: "One United States Pharmacopeial Digitalis Unit is identical in potency with the International Digitalis Unit, as adopted in 1928 by the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations. One International Digitalis Unit represents the activity of 0.1 Gm. of the International Standard Digitalis Powder." Powdered Digitalis of the U. S. Pharmacopeia XI is required to possess a potency of 10 U. S. P. units per gram and Tincture of Digitalis 1 U. S. P. unit per cubic centimeter. When these requirements were established it was generally believed that meeting them involved an increase in potency to 125 to 130 per cent of those official in the U. S. Pharmacopeia X (Edmunds, C. W.: The Potency of Digitalis Preparations of the 1936 Pharmacopeia, THE JOURNAL, July 22, 1939, p. 284).

The preparation of digitalis which was to serve as the new U. S. Pharmacopeia XI standard was prepared under the auspices of the Committee of Revision and then assayed against the 1926 International Standard Digitalis. When so examined it was found to be definitely stronger than the International Standard. When compared by the official one hour frog method in the laboratory of the chairman of the Subcommittee on Biological Assays, the late Dr. C. W. Edmunds, it was found that 0.745 Gm. of the United States Powder was equal in activity to 1.000 Gm. of the International Powder. This result did not create difficulty. It simply meant that 1 Gm. of the Pharmacopeial preparation Powdered Digitalis had to be equivalent in activity to 0.745 Gm. of the U. S. P. Reference Digitalis Powder instead of to 1.0 Gm.

However, there has not been universal acceptance of the correctness of this value of 0.745. Those who disagreed with Dr. Edmunds believed the Reference Digitalis Powder to be even stronger than he found it, which is another way of saying that his factor was too large. If this is true, then any digitalis preparation assayed against the U. S. P. XI Reference Digitalis Powder using this factor and meeting the Pharmacopeial requirement would actually be more than 130 per cent of the U. S. Pharmacopeia X strength. In the article by Bland and White which evoked this communication, the statement is made that "the majority of pharmacologists agree that by biological assay this increase in potency is approximately 25 to 30 per cent." I cannot speak for the majority of the pharmacologists, but most of the published biologic assay results indicate that the increase is something over 50 per cent, which brings the findings into line with those reported for clinical strength by Bland and White.

In 1939, because of a general feeling that the method of assay could be improved, a collaborative study was organized under the auspices of the U. S. P. XI of the assay of digitalis using frogs. At the request of the chairman of the U. S. P. XI Revision Committee, Prof. E. Fullerton Cook, and with the approval of Dr. Edmunds, chairman of the Subcommittee on Biological Assays, I have acted as chairman of this study. Gen-

erous collaboration has been received from university and manufacturing laboratories and the government control laboratories in both Canada and the United States. Studies by members of the group have confirmed the view that the present U. S. P. Reference Digitalis Powder is stronger than was intended.

Because of this fact, and also because of other characteristics which make the Reference Digitalis Powder unique, a new so-called "Study Powder" was prepared through the office of the chairman of the Revision Committee. This powder, a composite of assayed digitalis from a variety of sources, has now been extensively examined by several methods in a number of laboratories, and its characteristics are well known. The adoption of this powder as the standard of reference has been recommended to the Subcommittee on Biological Assays of the U. S. P. XII. The recommendation has been accepted, and when the powder has been adjusted to the potency of the International Standard, i.e., so that it contains 10 international units per gram, it is to become the Reference Digitalis Powder of the U. S. P. XII. The activity of all pharmacopeial digitalis preparations will continue to be expressed in terms of "Digitalis Units." One U. S. P. XII Digitalis Unit is to be the activity of 0.100 Gm. of this new Reference Digitalis Powder. Further, the comparison is to be made by the use of cats rather than frogs as the assay animal.

In the light of this explanation, qualification must be made of the statement by Drs. Bland and White, in footnote 6 of their paper, that in the twelfth revision of the U. S. Pharmacopeia the unit of potency has not been altered. The essential wording has perhaps not been seriously modified, although the U. S. P. XII will make it clear that the U. S. P. XII Reference Digitalis Powder is the reference standard, and that the published relationship to the International Standard is for purposes of information and not of definition. But the strength of the standard has been altered, and a new method of assay has been prescribed. These do in fact alter the unit.

The sole concern of the physician, however, is with the effect of these changes on the potency of official digitalis preparations. Practically all of the intensive studies of digitalis dosage were made prior to 1936, when the U. S. P. XI standards became effective. Most of the recent discussions have centered around the relationship of the U. S. P. XI digitalis potency to that of the digitalis in use prior to that time. How much stronger are present day preparations? What is to be the relative potency of the new preparations?

An answer to either of these questions presupposes a satisfactory knowledge of the strength of the earlier preparations. Exact information satisfactory to the biologic assayist is wanting on this point. However, there is adequate information on which to base a statement that should be satisfactory for those using digitalis in the clinic.

The U. S. P. XI Revision Committee intended to bring the official preparations of digitalis into conformity with international practice, which would have increased them to about 125-130 per cent of those previously official in the Tenth Revision. Actually those preparations which were adjusted to the new requirement have been found to be stronger than intended, running as high as 150 per cent. The U. S. P. XII preparations are to have the potency intended in the U. S. P. XI, namely about 125 per cent of those in use before 1936.

The implications of this statement should be emphasized. Official digitalis preparations of the U. S. P. XII will be somewhat weaker than those now current but will continue to be stronger than those of the period before 1936. This increase in potency must be recognized. The Revision Committee of the U. S. P. XII hopes that with the adoption of a new standard of reference, with a new method of standardization and with the greatly increased knowledge of biologic assays that has grown in part from attempts at solution of the controversial issues, this confusion may be cleared away. However, unless it is clearly

understood that there has been an increase in the potency of digitalis preparations official since 1936, this confusion will continue.

Digitalis preparations official under the U. S. P. XI, effective since June 1, 1936, are stronger than those of the U. S. P. X. Adoption of the proposed U. S. P. XII Reference Digitalis Powder and definition of the U. S. P. XII Digitalis Unit as the activity of 0.100 Gm. of this powder will result in a continuation of this increase in potency. Digitalis preparations official in the U. S. P. XII will have a potency equal to about 125 per cent of those in use prior to 1936. Since most clinical studies of digitalis dosage on which present practices are based were made before 1936, it is important that the medical profession recognize that both current digitalis preparations and those to be official in the forthcoming Twelfth Revision of the U. S. Pharmacopeia are stronger than those of the U. S. Pharmacopeia X.

TRANSFUSION OF BLOOD AND BLOOD SUBSTITUTES

To the Editor:—The concluding paragraph of the editorial "Transfusion of Blood and Blood Substitutes" (*THE JOURNAL*, November 8, p. 1627) contains the statement "The dried plasma promises to be the eventual solution of the problem for war emergency because of the greater stability, smaller bulk and the relative simplicity of packing, storing and transporting." This seems to me to be an oversimplification of the problem. The experimental and clinical studies in Great Britain and in this country have proved conclusively the efficacy of transfusions of plasma and serum in the first aid treatment of shock. Even shock accompanying hemorrhage can be treated successfully by restitution of the blood volume with serum or plasma, provided the bleeding is controlled. The personnel of the British Army Blood Supply Depot under the command of Col. L. E. H. Whitby has had a rare opportunity to study the treatment of shock in air raid casualties (Kekwick, A.; Maycock, W. D.; Marriott, H. L., and Whitby, L. E. H.: *Diagnosis and Treatment of Secondary Shock: A Study of Twenty-Four Cases*, *Lancet* 1:99 [Jan. 25] 1941). They found that from 2 to 6 pints (1 to 3 liters) of citrated plasma was required for the adequate treatment of shock accompanying hemorrhage. But they expressed the opinion that 1 of every 3 pints of fluid administered should consist of whole blood when large amounts of plasma were required. This was advised to obviate the further dilution of the recipient's erythrocytes and is supported by the experience of Scudder and Self (*Controlled Administration of Fluid in Surgery*, *New England J. Med.* 225:679 [Oct. 30] 1941).

But when death from shock has been averted by this treatment, the patient frequently faces the hazard of an urgent major surgical operation under general anesthesia. With the widespread use of blood transfusions in this country in recent years the opinion has been formed that patients with posthemorrhagic anemia tolerate operations much better if the oxygen carrying capacity of the blood is enhanced by the transfusion of erythrocytes. Blalock has stated that "every effort should be made to restore the red blood cell count and the blood volume to normal prior to operation" (*Principles of Surgical Care*, St. Louis, C. V. Mosby Company, 1940, p. 148). In large civilian general hospitals in this country about two thirds of all whole blood transfusions are administered to surgical patients. The indication for most of these transfusions is the correction of anemia before operation. Undoubtedly the same indication will prove

as frequent in military medicine. Plasma will not be suitable for this phase of the war emergency.

The recent development of blood substitutes for use in military medicine has resulted in much confusion for civilian practitioners. In warfare the ease of storage, transportation and administration of such products is a much more potent argument in their favor than it is in civilian practice, in which the facilities for laboratory procedures and refrigeration are adequate or easy to obtain. For the civilian hospital, methods are readily available for the manufacture from preserved whole blood of liquid plasma stored either at room temperature or in the refrigerator. The production and storage of frozen plasma is also feasible. Conclusive evidence has not been introduced to discredit any of these products.

In three places in the editorial are references to the fact that the use of plasma or serum obviates the necessity of typing and cross matching of bloods. Here again the argument which correctly carries great weight in military medicine has actually only slight application to civilian practice. Many physicians are impressed by the argument of the saving of time in an emergency because the laboratories on which they rely are employing time consuming methods for the typing and cross matching of blood. When the centrifugation technic of Landsteiner is used it is possible to type or cross match blood accurately in five minutes. By utilizing a blood bank in the University Hospitals of the State University of Iowa it has been possible to have whole blood running into the recipient's vein within fifteen minutes after the demand for a transfusion is made. During the interval mentioned, the recipient's blood group is determined and his serum and cells cross matched with those of an appropriate specimen in the refrigerator. Rabbit antiserum, now commercially available, indicates the group of the erythrocytes thirty seconds after it is mixed with the cell suspension. Preserved blood of group O can be administered to any recipient in an emergency without preliminary typing of the recipient or cross matching of the bloods. The addition of the recently developed A and B substances to the blood of group O neutralizes the agglutinins in the plasma and promises to obviate most of the objections to the employment of universal donor blood (Witebsky, Ernest; Klendshoj, N. C., and Swanson, Paul: Preparation and Transfusion of Safe Universal Blood, *THE JOURNAL*, June 14, p. 2654).

A consideration of civilian practices in the transfusion of plasma and whole blood is not entirely foreign to the war emergency. In this time of "total war," in which civilian casualties may be numerous, sources of readily available whole blood and plasma are extremely valuable to the community. They may serve as depots from which the military forces may draw. In times of peace there are myriad examples in which small community hospitals have suddenly been faced with the task of treating scores of victims of a railway wreck, an earthquake, a hotel fire or multiple automobile accidents. The presence of a blood and plasma bank may appreciably affect the mortality resulting from such disasters.

The development of methods by which whole blood can be preserved for thirty days in a refrigerator in a modified Rous-Turner dextrose-citrate mixture (DeGowin, E. L.; Harris, J. E., and Plass, E. D.: Studies on Preserved Human Blood: I. Various Factors Influencing Hemolysis, *THE JOURNAL*, March 9, p. 850) has made possible the operation of blood banks on a much smaller scale than is feasible when the time of preservation is shorter. At the expiration of the limit of storage the dilute dextrose-citrate plasma may be aspirated from the erythrocyte layer with a minimum of equipment and the plasma can be kept almost indefinitely in the refrigerator (Alsever, J. B., and Ainslie, R. B.: A New Method for the Preparation of Dilute Blood Plasma and the Operation of a Complete Transfusion Service, *New York State J. Med.* 41:126 [Jan. 15] 1941). This dilute plasma has been shown to be efficacious in the treat-

ment of shock (Besser, E. L.: Stored Dextrose-Citrate Plasma in the Treatment of Operative Shock, *Arch. Surg.* 43:451 [Sept.] 1941). The establishment of blood and plasma banks in thousands of smaller hospitals in the country not only would make these institutions more valuable in the treatment of the emergencies that arise in civilian practice but would also build a great military reserve which could be utilized much as the blood banks in cities in Great Britain are now being used in the treatment of air raid casualties.

ELMER L. DEGOWIN, M.D., University Hospital, Iowa City.

HEPARIN FOR PROLONGED COAGULATION TIME

To the Editor:—The remarks of de Takats in *THE JOURNAL* (Oct. 18, 1941, p. 1378) on the unusually prolonged coagulation time in our case of cavernous sinus thrombophlebitis treated with heparin are well received. Since this was the first case of this kind which we were fortunate enough to be able to treat with heparin, we attempted to approximate the regimen which had proved so successful in Schall's hands (*THE JOURNAL*, Aug. 23, 1941, p. 581). We are aware from the experience of others and our own subsequent experience that in cases of uninfected thrombophlebitis a coagulation time approximating twenty minutes seems to be adequate. However, in cases of septic cavernous sinus thrombophlebitis, in which the mortality is admittedly high and the prognosis always grave, it seems to us that a more prolonged coagulation time provides a greater margin of safety. We agree with de Takats that the complication which we encountered was due to the extremely high levels of coagulation time (three and four hours) which we attained. In any future cases we would attempt to avoid these extreme levels but still maintain a coagulation time considerably above twenty minutes.

It was not our intention to deter others from the use of heparin in any case of thrombophlebitis. Rather, we had hoped to help stimulate its more general use in these cases, but with a clearer realization of the occurrence of a complication which may ensue.

It remains for the future and the experiences of many observers to establish the optimum level of the coagulation time in these cases of septic thrombophlebitis.

SKIN TEST FOR DIAGNOSIS OF PREGNANCY

To the Editor:—It has recently been called to my attention by a number of physicians that a new cutaneous test for the diagnosis of pregnancy based on the report of Falls, Freda and Cohen (*Am. J. Obst. & Gynec.* 41:431 [March] 1941) is now being actively detailed by a commercial pharmaceutical organization as a "simplified, economical, reliable diagnostic skin test for pregnancy."

A recent report by Dr. Arnold F. Snyder and myself (*ibid.* 42:738 [Oct.] 1941) lists one hundred and fifty such tests using the exact technic described by Falls and his co-workers, in which an accuracy of only 75 per cent could be attained.

A word of caution should be interposed at this point in order to warn the practitioner not to be hasty in placing too much confidence in this reaction until further reports in the literature can support the contention of Falls and his colleagues in the accuracy of their test. Not only has the test been unreliable in our hands but a number of other investigators using smaller series of cases have informed me of the inaccuracy of this test in many instances.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY. *Written. Part I.* Various centers, March 31. Final date for filing application is Dec. 31. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York City.

AMERICAN BOARD OF INTERNAL MEDICINE. *Oral.* April in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY. New York, June. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY. *Written. Part I. Group B.* Various centers, Jan. 3. *Oral. Part II. Groups A and B.* Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OTOLARYNGOLOGY. *Oral and Written. All Groups.* Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PATHOLOGY. St. Louis, March 30-31. Final date for filing application is Jan. 30. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS. *Oral.* Los Angeles, April 22, preceding the Region IV meeting of the American Academy of Pediatrics. Cleveland, May 13, preceding the Region III meeting of the American Academy of Pediatrics. *Written. Locally.* February 14. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF RADIOLOGY. *Oral. All Groups.* Atlantic City, June 4. Final date for filing application is April 1. Sec., Dr. Byrl R. Kirklin, 102 110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY. *Written.* Various centers, December. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Illinois June Report

The Illinois Department of Registration and Education reports the written examination (graduates of foreign schools given also a practical test) for medical licensure held at Chicago, June 24-26, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Three hundred and twenty-eight candidates were examined, 310 of whom passed and 18 failed. The following schools were represented:

Arizona October Report

The Arizona State Board of Medical Examiners reports the written examination for medical licensure held at Phoenix, Oct. 7-8, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Eight candidates were examined, all of whom passed. Five physicians were licensed to practice medicine by reciprocity and 1 physician was so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Liability of Medical Service Corporation for Negligence of Employees.—One of the defendants, a hospital association incorporated for profit, contracted with the Washington High School of Portland, Ore., "to provide medical and surgical and hospital services, . . . for the members of the football squad of the school." The plaintiff, a member of the school's football squad, injured his left shoulder and arm in games on Sept. 14 and Sept. 20, 1935. The day after the second game he visited the hospital association's offices and was given medical attention by one of the other defendants, Shields, a physician employee of the association. Shields made a diagnosis of an "acromioclavicular bruise," gave the boy analgesic balm to apply to the shoulder if he should ever again suffer a similar injury and advised him that he could continue to play football. Apparently the plaintiff had suffered a dislocation of the left shoulder and in playing in succeeding games suffered repeated dislocations, consulting employees of the association following several such injuries, but the condition remained undiagnosed. By the following August the shoulder and arm were in such a condition that surgery was the only available remedy. Eventually he brought an action for malpractice against the hospital association, two physician employees, Shields and Sisson, and a lay employee, Jones. The trial court sustained a motion for nonsuit as to the lay employee but denied it as to the other defendants. The jury found in favor of the plaintiff and, from judgment on the verdict, the hospital association and the physicians appealed to the Supreme Court of Oregon.

It was first contended that the defendant hospital association was not liable for any negligent acts performed by the defendant physicians because the physicians were independent contractors rather than employees of the association. The association, it appeared, was organized under the laws of Oregon to furnish medical, surgical and hospital services for profit. The defendant physicians were paid a monthly salary by the company and were furnished office space in the company offices. They were permitted to have their own patients but, in the offices furnished them, they rendered the professional services which the company agreed to furnish under its various contracts. Obviously, said the Supreme Court, under the circumstances, the relationship existing between the association and the physicians was that of master and servant and the association, by the doctrine of *respondeat superior*, is liable for the physicians' negligence. The association argued that the very nature of a physician's services precludes the physicians from being subject to the association's control and therefore makes the physicians independent contractors. While, answered the Court, in many instances the relationship between the parties may be tested by the right or lack of right to exercise control over an agent as to the manner and details of his work, in a case of this kind such a test cannot be determinative, since the test must give way to the rule that one cannot absolve oneself of contractual obligations by devolving the performance of those obligations on a stranger to the contract. If the hospital association has provided services in a negligent manner, it has not complied with its contractual obligations and it cannot secure immunity from liability for the negligence of the physicians it employed to perform its contractual obligations by pleading that it exercised due care in the selection of those physicians.

It was next contended that there was no evidence of malpractice against the association and the defendant Shields. The plaintiff testified that on September 21, the day after his second injury, he visited Shields in the office furnished by the defendant company and told him that in a football game on September 14, when a pile of players got off of him, it felt as though his shoulder had been broken because "the bone was sticking out, it felt like," that two of the officials of the game snapped it in

some way and it seemed to jump back in place, and that a similar injury was sustained in the game on September 20. The plaintiff then testified that Shields examined his arm, diagnosed his condition as an acromioclavicular bruise, gave him some analgesic balm to use if the same injury occurred again and told him that he could continue to play football. A physician, called by the defendants, on the basis of a history of the case given to him in August 1936, testified that at that time he made a definite diagnosis of recurrent dislocation of the shoulder and recommended an operation as the only remedy for the condition then existing. While, said the Court, there was no evidence that, in his examination of the plaintiff, Shields failed to use the tests approved by standard medical practice, it does not, however, necessarily follow that he was not guilty of negligence. There was medical testimony from which the jury could have found that the plaintiff, in recounting his injuries to Shields, described, characteristically, a dislocation of his shoulder, and therefore, the jury could have found that a physician, exercising ordinary care and skill in making his diagnosis, should have discovered the true nature of the plaintiff's ailment. It was conceded that the proper treatment for a recent dislocation of the shoulder was immobilization of the shoulder and arm for a period of time and that advice to the patient to play football would be highly improper. If, therefore, as the plaintiff testified and Dr. Shields vigorously denied, such advice was given, the evidence was sufficient to take the case to the jury, and the court committed no error in denying the motions for nonsuit and directed verdict with respect to the hospital association and Shields.

With respect to another one of the physician defendants, Sisson, the Court held that there was no evidence tending to prove that any act on his part was the proximate cause of the plaintiff's injury. The plaintiff contended, however, that since he had sued the defendants jointly, if negligence was proved with respect to any defendant, Sisson was necessarily also liable. The Court held, however, that in this case, essentially, the corporate defendant, the hospital association, had been sued for tort and with it were joined as defendants the corporation's employees who were charged with acting on its behalf in the commission of the wrongful acts. An employee cannot be held liable for the acts of a co-employee, said the Court, if he in no way participated in the acts on which the liability is sought to be predicated. Consequently Sisson's liability turns altogether on what he himself did or failed to do and he could in no wise be held responsible for the negligence of Shields. The Court accordingly held that the case should be dismissed as to Sisson.

At the trial, a witness called by the plaintiff was permitted, over objection, to testify that it was the policy of the high school concerned not to allow a boy to play football unless the hospital association "said it was all right to use him." The admission of this evidence, the Court held, was erroneous. The contract, said the Supreme Court, between the hospital association and the high school contained no provision requiring the company to keep the school authorities advised as to the physical condition of all the members of the football squad or to instruct the high school officials not to permit a boy to play because of his physical condition. The effect of the objectionable testimony was to inject into the case an issue not justified by the terms of the contract and not tendered by the plaintiff's complaint. Without this issue the whole case of the plaintiff depended on his unsupported testimony that Dr. Shields had advised him to continue playing football. If the jury believed Dr. Shields as against the plaintiff, it must necessarily have found for the defendants, because a wrong diagnosis in itself creates no liability. Since the testimony was received one may presume that it was commented on in argument, and, since there was no claim on the part of the defendants that any of them had advised the school authorities to have the plaintiff discontinue his football activities, prejudice to the defendants' case in all probability resulted.

The judgment was accordingly reversed and the cause remanded to the trial court with directions to enter a judgment of nonsuit in favor of Sisson and, apparently, to proceed with a new trial with respect to the hospital association and Shields. —*Ginsli v. C. H. Weston Co.*, 108 P. (2d) 1070 (Ore., 1941).

Malpractice: Alleged Failure of Dentist to Cure After Extraction and Discovery of Necrosis of the Mandible.—Fred Specht consulted the defendant dentist, Jan. 29, 1940, relative to a "loose tooth." After an examination, but without taking roentgenograms, the dentist extracted the tooth and discovered that his patient was suffering with necrosis of the mandible. Just what treatment, if any, the dentist then undertook, the reported decision does not make clear. The patient became ill with "systemic infection or streptococcus from which he died on February 6, 1940." The patient's mother instituted an action for damages against the dentist, alleging that in caring for her son the dentist had failed to exercise the care required of him by law in that before the extraction the dentist failed to have a proper roentgenogram taken, that the dentist failed to use sanitary, clean and sterilized instruments in the probing and extracting of the tooth and its root, that although the dentist discovered after the extraction that the decedent had a necrosis of the mandible and was in great danger of infection he failed to send decedent to a hospital to have the cavity properly curetted and failed himself to curet "properly, sanitarily, and sufficiently," and that the dentist negligently allowed his patient to become ill with "systemic infection or streptococcus" from which he died. The trial court sustained a general demurrer to the complaint and the decedent's mother appealed to the court of appeals of Georgia, division 2.

The Georgia code, section 84-924, said the court, requires a person professing to practice medicine or surgery for compensation to bring to the exercise of his profession a reasonable degree of care and skill. Any injury resulting from a want of such care and skill is a tort for which a recovery may be had. These provisions of the code apply also to a licensed dentist in the practice of his profession. The standard prescribed by the code when applied to the facts and circumstances of any particular case must be taken and considered to be such a degree of care and skill as, under similar conditions and like surrounding circumstances, is ordinarily employed by the profession generally. Not only must a dentist possess the requisite care and skill but he must exercise these qualifications. A dentist is not an insurer or warrantor that the exercise of his professional judgment will effect a cure of the patient. Nor is he obliged to bring to the exercise of his profession the utmost skill. If he measures up to the qualifications and applies the reasonable care and skill legally required of him he is not responsible for a mistake of judgment. If, however, an error of judgment is so gross as to be inconsistent with that degree of care and skill which a dentist should possess and exercise, liability may result when an injury is produced. A dentist in practicing his profession is under duty not only to use the requisite care and skill in a particular operation but also to give such after-treatment to the patient as the necessities of the case demand, in the absence of any special agreement to the contrary. Applying the aforestated principles of law, continued the court, to the facts alleged in the present petition, that in extracting the root of a tooth of the decedent the dentist negligently failed to use sanitary instruments and, on discovering that the jawbone of the patient was diseased and in great danger of infection, negligently failed to curet the cavity or to send the patient to a hospital for such after-treatment, in consequence of which alleged negligence "systemic poisoning or streptococcus" developed in the jawbone, causing the death of the patient, a jury question was presented as to whether or not the dentist was guilty of such gross error of judgment as to amount to a failure to exercise the requisite care and skill toward the patient, and the trial court erred in sustaining the defendant's general demurrer to the petition. The court accordingly reversed the judgment of the trial court in favor of the dentist.—*Specht v. Gaines*, 16 S. E. (2d) 507 (Ga., 1941).

Malpractice: Death from Pulmonary Embolism Following Tonsillectomy and Turbinectomy.—The patient underwent an operation for the removal of his tonsils and the turbinated bones of his nose, the operation being performed by a physician employed by the patient. A hospital resident physician, an anesthetist and an instrument nurse assisted in the operation. About five hours after the completion of the operative procedures the patient died, death being attributed to "pulmonary embolism of the left upper lobe of the lung, with an

infarct of the same upper lobe." Thereafter the widow and the son of the deceased patient brought suit against the hospital, the operating physician, the resident physician, the anesthetist and the instrument nurse. The trial court directed a verdict for the defendants and the plaintiffs appealed to the Court of Appeals of Maryland.

The operation was performed under a general anesthetic and an ether tube was used. The plaintiffs' evidence tended to show that this tube was left, unfastened, in the patient's mouth when he was returned to his room and that several hours later a friend visited the patient and found him unattended, "fighting for his breath" and waving "his hands in a frantic way." The patient died two hours later. The apparent contentions in this case were (1) that the defendants were negligent in permitting the ether tube to remain untied in the patient's mouth which "allowed the blood, serum and mucus to run down into the windpipe, clot, and stop the air from passing to the lungs," resulting in the patient's death and (2) that the patient was negligently left unattended in his hospital room after the operation. Before the plaintiffs can recover against any of the defendants, the Court said, it must be shown by affirmative evidence that they were either unskilful or negligent in their respective capacities and that such want of skill or care resulted in the death of the patient. "To constitute actionable negligence, there must be not only causal connection between the negligence complained of and the injury suffered, but the connection must be by a natural and unbroken sequence,—without intervening efficient causes,—so that, but for the negligence of the defendants, the injury would not have occurred. It must not only be a cause, but it must be the proximate cause." 22 R. C. L. 113.

The evidence in the record, the Court continued, pointed to no specific act of negligence on the part of any of the several defendants. Negligence, if any, must therefore be imputed from the fact that the patient was found gasping for breath, without an attendant or nurse in attendance in his room. But, said the Court, there was no evidence to show that, in the absence of the employment by the patient of a special nurse or attendant, it was incumbent on any of the defendants to see that an attendant was at his bedside at all times. Not only was there no evidence tending to prove any negligence on the part of the defendants, acting either collectively or in their several capacities, but the record contained affirmative testimony showing the proximate cause of the death to have been pulmonary embolism, such evidence being introduced at the instance of the plaintiffs. In the opinion of the Court, there must be something more than a showing that the evidence might be consistent with the plaintiff's theory of the cause of death. It must be such as to make that theory reasonably probable—not merely possible—and more probable than any other hypothesis based on such evidence. To justify a judgment for the plaintiffs, the Court said, the evidence must warrant an inference that the death resulted from the negligence of the defendants, or at least some one or more of them, rather than from some other cause. Since in the opinion of the Court the evidence in this case did not warrant such an inference, the action of the trial court in directing a verdict for the defendants did not constitute error.—*State, for Use of Kalivas v. Baltimore Eye, Ear and Throat Hospital, Inc.*, 10 A. (2d) 612 (Md., 1940).

COMING MEETINGS

Annual Congress on Industrial Health, Chicago, Jan. 12-13. Dr. C. M. Peterson, 335 North Dearborn St., Chicago, Secretary.

American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Dively, 1103 Grand Ave., Kansas City, Mo., Secretary.

American Association for the Study of Neoplastic Diseases, Washington, D. C., Dec. 18-20. Dr. Eugene R. Whitmore, 2139 Wyoming Ave., N.W., Washington, D. C., Secretary.

Society of American Bacteriologists, Baltimore, Dec. 29-31. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore 11:677-740 (Sept) 1941

- *Human Infection with *Pasteurella Pseudotuberculosis* Rodentium of Pfeiffer. Report of Case. Emma S. Moss and J. D. Battle Jr., New Orleans—p. 677.

- Autopsy Permit. O. Saphir, Chicago, and C. A. Hellwig, Wichita, Kan.—p. 733.

***Pasteurella Pseudotuberculosis* Rodentium Infection.**—Moss and Battle cite the sixth recorded case of human infection by *Pasteurella pseudotuberculosis* rodentium (Pfeiffer). The patient was a mulatto aged 34. The only history of contact with rabbits that could be established was that he had eaten cooked rabbit three weeks before. The strain of *Past. pseudotuberculosis* rodentium, isolated before death from the blood stream and after death from the blood stream, the spleen and an abdominal lymph node, was pathogenic for white mice and guinea pigs. The organism was recovered from the peritoneal exudate of the heart blood of the animals dying of the infection.

Hematologic Values in the Elderly.—According to Fowler and his colleagues, hematologic study of subjects aged 65 to 80 shows a slight reduction from the normal in the hemoglobin, erythrocyte and hematocrit values. The degree of the reduced erythrocyte count and hematocrit readings are in accord with the hemoglobin reduction, suggesting that a moderate anemia is present. Even at this age the values in women were slightly and consistently lower than those in men.

Pulmonary Atelectasis.—Niemeyer believes that in many localities postoperative pulmonary atelectasis is still being considered as pneumonia. Follow-up study certainly bears this out, as unrelieved atelectasis often will terminate as pneumonitis or pneumonia. The idea is too prevalent that the only true expression of this condition has, as its minimal lesion, a complete lobar collapse with its mediastinal shift, and thus the minor lobar involvements are not recognized, although they do but rarely cause death they contribute considerably to postoperative morbidity and in some instances lead to pneumonia. A sudden

elevation of temperature in the first twenty-four postoperative hours, with an exaggerated rise in pulse and respiration, should suggest atelectasis. Inhalation anesthesia given to patients with productive processes in the lungs and operation on the upper part of the abdomen should be considered as potential sources of pulmonary atelectasis, and postoperative prophylactic measures (thinning the bronchial secretions, assisting in expectoration by posturing, coughing and reexpansion of the collapsed lung by deep respirations) should be instituted immediately.

Murine Origin of Typhus Epidemics.—Liu and Zia report that during an epidemic in a household they isolated two typhus strains from mice and mouse fleas and a third atypical murine strain from body lice of one of the patients. This isolation, they believe, justifies the view that in China, as in Mexico, the human body louse may under favorable circumstances transmit the murine rickettsia from man to man, giving rise to epidemics. In their household epidemic they found that in less than a month 8 of 9 persons living in the same house had contracted the disease. The house was heavily infested with mice, the mud floor showing many holes. There were no cats or dogs. The ninth member of the household at no time throughout the outbreak showed any signs of indisposition. All the members admitted that they harbored body lice through the greater part of the year and not infrequently noticed fleas in the clothing and bedding.

Agglutinin in Human Blood.—Landsteiner and Wiener describe a test for determining the presence or absence of the new agglutinin (Rh), inherited as a simple mendelian dominant, in typing patients and prospective donors. The method for determining suitable serums consists in making serial dilutions by halves and testing with known negative and positive blood. Serums which show in three (or more) successive dilutions negative reactions with the former and positive ones with the latter blood are usable. Actual tests can be carried out by selecting a dilution of serum, e. g. 1:10, which gives no reactions with negative but definite reactions with positive blood, those serums that contain appreciable amounts of anti A or anti B agglutinins having been previously absorbed with small quantities of A and B blood. The blood to be tested should be fresh. An alternative method is to absorb the serums diluted, e. g. 1:4, with a quantity of blood (using A or B cells if indicated) sufficient to remove the reaction with Rh negative blood. Two drops of the test fluid are mixed with 1 drop of 2 per cent (in terms of blood sediment) freshly prepared washed blood suspension in a narrow tube and allowed to stand at room temperature. Readings are taken, after sedimentation has occurred, by direct lens inspection of the bases of the tube. Negatively reacting blood shows a circular deposit with a smooth edge, and positive blood has a wrinkled sediment with a serrated border or shows a granular deposit. A further microscopic examination in two hours, the sediment again being inspected after the tubes are gently shaken, will reveal negative blood samples to be homogeneous, and the positive ones will show various degrees of agglutination, frequently visible to the naked eye. The blood of 448 white persons was examined with

guinea pig and/or human serums; the blood of 379 was positive and that of the others negative, that is, 84.6 per cent were Rh+ and 15.4 per cent were Rh—. The blood of only 9 of 133 Negroes gave clearly negative reactions. This suggests the possibility of a racial difference in Rh distribution.

Dental Defects in Draftees.—East studied the data of physical examinations of draftees of two wars and the present national emergency. Defective and deficient teeth caused the rejection of 24.2 men per thousand in 1918. The rejection rates ranged from 102.85 per thousand for Vermont to 2.9 for Arkansas. Differences in criteria probably do not explain the

entire variation in rates. Dental defects defined as "loss of teeth" also played an important part in physical unfitness among the men drafted for the Northern army in the war between the states. The 1863 and 1864 draft data (Lewis, 1865) reveal that the highest rejection rates for dental defects then as in 1918 were in men from the New England states. The differences in rejection rates for the different areas in 1863 and 1864 and in 1918 correspond closely to rates of carious permanent teeth among the school children of twenty-six states examined in 1933 and 1934. The preliminary report from one hundred and twenty New York Selective Service boards shows that "missing teeth" were the most frequent cause for rejection. There is considerable evidence that the dental health of the population, as measured by physical fitness for military service, is growing worse instead of better despite a per capita increase in dental colleges and dentists and the recent extensive federal, state, city and private public dental health programs. Evidently the methods advocated and used for the last eighty years have not been sufficient to cope with dental diseases, particularly tooth decay. Since tooth formation is influenced during prenatal life, infancy and early childhood all agencies and professions concerned with maternal and child health have responsibilities and opportunities in research, education and practice in the field of dental health.

Neurocirculatory Compression.—According to Spurling and Grantham, about 75 per cent of all patients with painful arms and shoulders (primary scalenus neurocirculatory compression) seen in the acute stage of the disorder have been improved or become asymptomatic after conservative treatment by keeping the arm up above the shoulder level with the hand behind the head as much as possible during waking hours and, if feasible, sleeping with the arm thus elevated. Tying the wrist to the head of the bed is a good way to maintain the posture during sleep. The local application of heat (the infra red lamp) over the scalenus muscle and the shoulder is also advised. Diathermy may be used if convenient. Operation is advised only for patients who fail to improve with reasonable conservative treatment.

Neurology. J. B. Ayer, Boston.—p. 452.

Tuberculosis of Sternum.—Wassersug discusses a series of 12 patients with tuberculosis of the sternum encountered among 1,134 with tuberculosis of bones and joints admitted to the Lakeville State Sanatorium between 1926 and 1940. Seven of the 12 were females and 5 males, and their ages varied from 1½ to 70 years. A history of trauma was not elicited, although 5 had had definite contact with tuberculosis. Eleven patients had other tuberculous foci. Tuberculosis of the sternum must be suspected when a swelling develops on the anterior wall of the chest in a patient with other tuberculous foci. The swelling was painless in 7 and painful in 3; in 2 a discharging sinus was the chief complaint. Eventually, one or more draining sinuses develop in every patient. Sternal tuberculosis must be differentiated from tuberculosis of the wall of the chest, ribs and costal cartilages. The tuberculosis of the sternum in 3 patients became arrested spontaneously, and the sinuses healed. In the others a variety of operative procedures was performed. The end results were usually good. Two patients are still hospitalized, and 1 died while in the sanatorium. Of the 9 discharged patients, 2 have died (1 of pulmonary tuberculosis and 1 of arteriosclerosis) without recurrence of the disease in the sternum. A third patient was taken by one of his parents to China and probably died en route. The remaining 6 patients were followed from ten months to eleven years and three months. Only slight drainage persists in the 1 patient followed for ten months. None of the other patients have had any recurrence of the disease in the sternum. All sinuses have remained healed, and there has been no swelling, pain or tenderness. However, 1 of the patients has far advanced pulmonary tuberculosis, and 1 has been bedridden for three years because of a cerebral hemorrhage. With regard to the deaths, tuberculosis of the sternum could not be regarded as a cause.

Massive Gastric Hemorrhage.—McMillan states that few medical emergencies are as hazardous as gastric hemorrhage. After the shock from the loss of blood has been compensated the cause of the hemorrhage and its extent should be determined by diligent laboratory studies and a careful history. About 90 per cent of gross gastric hemorrhages result from erosion of a vessel in the base or the margin of a peptic ulcer. The author's procedure has been to keep the patient drowsy with opiates or soluble phenobarbital, giving only small amounts of cracked ice by mouth for eight to twelve hours and then 1 ounce (30 cc.) of whole milk and 1 of cream every hour. On the second day 3 ounces (90 cc.) of a thin plain gelatin solution is given three times a day along with the milk and cream. On the third day small amounts of soft boiled eggs, cereal and toast are added, and thus the diet is increased gradually. As a rule the patient's extreme anxiety is promptly allayed and he often sleeps without sedatives. Usually bleeding stops promptly and the signs and symptoms of shock disappear rapidly. One of the greatest and most frequent errors is to give blood transfusions too soon. Giving transfusions during active bleeding results in about a 20 per cent mortality. They are indicated only if the hemoglobin level falls to 30 per cent or the falling

systolic blood pressure is 90 mm. of mercury or less, when about 250 cc. of citrated blood should be given slowly by the drip method. The low blood pressure is nature's protecting mechanism against further bleeding. Routine early surgical intervention results in a mortality of about 15 per cent, although Lahey, operating only on patients more than 40 years of age, reported a 5 per cent rate. Operation on patients with ulcer is indicated only when bleeding is recurrent or when perforation, deep penetration, obstruction, evidence of a malignant growth or gastric ulcer which after three weeks of medical treatment is still 2 cm. or more in diameter exist. The author cites 12 cases of massive and 3 of moderate gastric hemorrhage. Three patients died. The 12 who survived were given a modified Meulengracht regimen early after bleeding. Of the 3 who died, 1 received repeated small transfusions and no food, 1 died of pulmonary embolism about twelve hours after gastric resection and 1 died of postoperative peritonitis following gastric resection for a highly malignant carcinoma. None of the patients fed early died except as a result of operation performed later on.

Serum Antibodies and Susceptibility to Influenza.—

Rickard and his co-workers determined the neutralizing capacities of acute phase and convalescent serums against influenza A and B viruses in patients in whom the diagnosis of influenza was established by laboratory tests. The data of the study show that there are correlations between the different levels of specific neutralizing antibodies and susceptibility or resistance to the infection by the different etiologic agents of influenza. However, high antibody levels against influenza A virus do not diminish the frequency of influenza B or vice versa. Influenza of unknown cause appears to occur with somewhat increased frequency among persons who possess considerable concentrations of antibodies against both influenza A and B viruses.

Complex Vaccine Against Influenza A.—

Horsfall and his co-workers present evidence that a single subcutaneous injection of the complex vaccine (prepared from chick embryos inoculated with influenza A virus and the X strain of canine distemper virus) four months prior to an epidemic of influenza caused a significant reduction in the incidence of influenza A among vaccinated persons. During October 1940 7,907 volunteers of a population of 17,595 in fifteen state institutions in Florida and Alabama were given the complex vaccine. The 9,688 persons who were not vaccinated were considered as normal controls. Approximately four months after the vaccine had been given, epidemics of influenza occurred in ten institutions, with a total of 1,450 cases of influenza. In four institutions (in which volunteers received a vaccine producing about one tenth as many antibodies as the vaccines used for the other volunteers) clinical influenza occurred in 11.4 per cent of control and in 9.3 per cent of vaccinated persons, and for the other six institutions the respective figures were 8.3 and 5.6. The available evidence indicates that no level of antibodies possessed by normal persons, even though it is high, can be taken to indicate complete immunity to influenza A. The disease was less frequent in persons with high antibody levels but it did occur. The fact that the incidence of influenza of unknown cause was not significantly reduced among the vaccinated persons is additional evidence for the specific relationship between antibody levels against one influenza virus and the probability of the occurrence of infection by the homologous virus.

- Girl Born Without Legs and Without Arms: Report of Case. J. L. Levy, Clarksdale, Miss.—p. 1085.

Gunshot Wounds of Pregnant Uterus.—For the thirty years since 1910 Bost finds that 9 cases of gunshot wounds of the uterus during pregnancy have been reported. He cites the tenth case. Unlike concurrent disease and trauma pregnancy apparently offers a protective mechanism against gunshot wounds. The mortality (1 of the 10 mothers died, and of the 6 viable infants 2 died) appears to be much less than the general mortality from gunshot wounds of the abdomen. Indications for opening the abdomen appear to be the same as though the pregnancy did not exist. When the abdomen is explored and no serious injury to the viscera is found except to the uterus the general opinion is that the uterus should be emptied by cesarean section if the uterine cavity has been penetrated. However, hysterectomy was done "to arrest pelvic hemorrhage" for 2 patients, 1 was operated on (the bullet was removed and the child delivered normally seventeen days later) and 1 was not operated on and labor came on and a living child was delivered normally three days later. The author's case illustrates the importance of a flat roentgenogram when there is no exit wound to determine the course of the bullet so that the proper incision can be predetermined. It shows also that a negative urinalysis does not rule out injury to the bladder.

Acne Vulgaris.—Sutton believes that an acne lesion, shallow or deep, is a foreign body reaction to oily epidermal material and suggests seborrhea. Comedo and acne vulgaris are analogous to diabetes mellitus. In diabetes, an excess of carbohydrate collects beyond the body's ability to metabolize it. In acne, an excess of lipid collects, provoking pustular foreign body reactions; acne is controllable by reducing lipid intake and enhancing lipid metabolism, if necessary, by giving thyroid. Acne vulgaris in the author's opinion is a pustular lipidosis. A carefully designed low fat diet, under supervision, is effective in diminishing seborrhea. No ill effects in more than 400 patients with acne have followed such diets. The patients had definite relief from fatigability, constipation and mental depression, while at the same time their acne improved. The constitutional symptoms of patients with ordinary acne are due to their relative hypothyroidism. By "relative" the author means the inadequacy of the autochthonous hormone to cope with the quantity of lipid ingested. Constipation is not a cause of acne; patients with acne are constipated for the same reason that they have acne, menstrual difficulties, anemia and "that tired feeling." These are all accompaniments of hypothyroidism. Thyroid is given to all patients. Objective improvement, diminution of seborrhea, is visible in a week. Improvement is obvious in a month, and from three to six months are required for cure. The diet is tentatively broken after the skin has become normal, being enriched particularly in vitamin A, and the patient determines by experiment what his lipid tolerance is.

*Varicella and Herpes Zoster: Report of Three Illustrative Cases. R. M. Campbell.—p. 91.

Varicella and Herpes Zoster.—Campbell reports 3 cases in which the vesicular eruptions characteristic of herpes zoster and chickenpox appeared concurrently. Only 1 patient was a child, following whose illness an outbreak of chickenpox affected 13 children in a ward. Sources of infection other than the infant with coexisting herpes zoster and varicella were excluded. The author believes that the unicist theory, that the viruses of the two diseases are one and the same, is inadequate to explain the facts. The absence of regular cross immunity is a serious objection to such a close interrelationship of the viruses of herpes zoster and chickenpox.

*Scabies Treated by Benzyl Benzoate Emulsion. I. F. Mackenzie.—p. 403.

*Transmission of Scabies. K. Mellanby.—p. 405.

Sulfur Lather Tablets for Scabies.—Carter adds a method to the list of sarcopticides which she believes has certain advantages over other methods, especially in children. The principle of the treatment was first described in America (Nolan, 1937), but instead of using sulfur soap as Nolan did the author used a tablet in which the amount of sulfur suggested as adequate, 0.72 Gm., was incorporated with a lathering agent. The lathering method is effective, especially in children, and the chance of dermatitis seems to be negligible in that the patient is given three tablets and treatment can be carried out at home without the fear of overtreatment by the zealous minded. Scrubbing was not necessary for children, in whom a hot bath and a rub-down with a flannel cloth was sufficient. None of the children complained of pain after lathering, even those with denuded or septic areas. However, the author concludes that the basic problem lies in preventing the rapid spread of the disease, and this means control and treatment of contacts and the reservoir of untreated persons. This involves inspection and treatment of every member of a family in which scabies has occurred, and also the immediate disinfection of all their clothing and bedding. If this was applied only to school children the plan would be effective in reducing materially the incidence of scabies.

Benzyl Benzoate Emulsion for Scabies.—Mackenzie believes that the increase in scabies presents a problem of considerable complexity and of no little importance to the maintenance of the sustained national effort demanded at the present time. In a group of patients recently treated by him there was a relatively high proportion of affected families with no history of previous infection. He discusses the results obtained with a benzyl benzoate emulsion ("proscabin," Bayer). After a hot bath, the body having been well lathered with soap and scrubbed, the skin was dried and proscabin was brushed on the whole surface of the body. Badly affected parts were repainted immediately after the first application had dried. The previously worn clothing was then put on. The bath and painting were

repeated on the second day and clean underwear was used. Parents were advised to change and disinfect their bedclothes. Two days later the patient was examined, and when treatment had been successful it was usual to find that scratching had ceased and that the most affected areas looked dull and brown in contrast to the many bright pinkish points normally distributed in the scratched areas. The crusted or pustular areas of secondary infection were treated with a 1 per cent ammoniated mercury ointment, after the two proscabin treatments. A second and third course of two treatments may be deemed necessary for some persons. The author suggests that the handling of infested articles (books, towels and so on) by uninfected school children may be a means of carrying scabies to previously uninfested households.

Transmission of Scabies.—Mellanby describes experiments determining exactly how scabies is normally transmitted. The experiments were made on volunteers (pacifists) living under controlled institutional conditions who agreed to submit to infection and to allow the course of the disease to be followed on their persons. The volunteers used bedding and underclothing from one to seven days after they had been used by patients with scabies and beds and underclothing immediately after being vacated and removed by patients with scabies. The men were inspected daily for about a month (sometimes longer) after each experiment. Two volunteers finally became infected, and thus it was possible to test the effects of personal contact. Four uninfected volunteers slept in beds with men with scabies. In 3 instances the volunteer and the infected man slept together for seven nights, and mites were found on all 3 volunteers after eight, nine and twelve days from the start of the experiment. Scabies did not develop in the fourth volunteer, who slept under these conditions for two nights. The author believes that scabies is normally transmitted by slight personal or venereal contact. He believes that one reason for the importance attached to fomites in the transmission of scabies is that lice are known to be spread by this means. He thinks that the evidence presented is not sufficient to say that disinfection of clothing and blankets is unnecessary in cases of scabies, though the conclusion seems probable. When reinfestation of a patient is being attributed to fomites the following possibilities should be excluded: contact with another person with scabies, incomplete cure and as certain lesions remain visible and irritant for weeks after cure reinfestation or relapse cannot be stated to have occurred unless living mites were found.

*Treatment of Influenza, of Lacunar Tonsillitis and of Otitis Media with Sulfathiazole. K. Sigg.—p. 935.
Leprosy. W. Racine.—p. 936.

Sulfathiazole in Influenza, Tonsillitis and Otitis.—Sigg employed sulfathiazole in 28 cases of influenza, 8 cases of lacunar tonsillitis and 12 cases of otitis media. It is noteworthy that the patients with influenza always show critical defervescence after sulfathiazole therapy. The temperature becomes normal in forty-eight hours. The rapid fever reduction is especially evident in the patients who have had fever for some time before the administration of sulfathiazole. In tonsillitis and otitis, the action of sulfathiazole is proved not only by the behavior of the temperature but by the disappearance of the tonsillar coating and of the redness of the tympanic membrane. In lacunar tonsillitis, the fever subsides in thirty to forty-eight hours, irrespective of the stage during which the sulfathiazole treatment is begun. The tonsillar coating disappears in two to three days, that is, the patient feels subjective improvement before the objective signs have subsided. In otitis media the fever disappears from twenty-four to thirty-six hours after onset of the sulfathiazole medication. While perforation of the tympanic membrane or running of the ear occurred in none of the 12 patients with otitis media treated with sulfathiazole, the author saw 3 patients with otorrhea for whom sulfathiazole had not been used; however, these too were cured without further local treatment when sulfathiazole was given. The author recommends large initial doses. He gives 4 or 5 Gm. on the first day, 3 Gm. on the second, 2 Gm. on the third and 1 Gm. on the fourth day. If there is no reduction in temperature at the end of the first day the larger dose given on the first day must be continued. The doses can be smaller for children. In patients with influenza the medication may cause vomiting, but sulfathiazole causes no other undesirable effects.

- *BCG Vaccine Against Tuberculosis. R. de Carvalho Loures.—p. 43.
BCG Vaccine.—De Carvalho Loures reports his personal experience in vaccinating 651 newborn infants from 1938 up to 1940 with BCG vaccine. He concludes that the BCG vaccine is harmless, has no contraindications and protects infants against tuberculosis and other infections. The vaccine should be given as a routine to all newborn infants, preferably during the first ten days of life. Isolating the infants after vaccination for a given time is necessary, but the impossibility of isolating them is not a contraindication for administration of the vaccine. Infants of poor families, among whom tuberculous contacts are frequent, should be vaccinated by all means. The appearance of tuberculin allergy is the indication of the use of the vaccine by the body. Prevention against tuberculosis is maintained by repeating vaccination at certain intervals.

Revista Médica de Rosario, Rosario de Santa Fe**31:619-720 (July) 1941. Partial Index**

- *Myxedema Heart. L. González Sabathie, V. S. Terán and C. Vidal.—p. 619.
Thrombosis of Pampiniform Plexus in Vaquez Disease. R. Ercole, T. C. Minnhaar and A. Fort.—p. 644.

Myxedema Heart.—González Sabathie and his collaborators observed the behavior of the heart and of the blood pressure in 15 patients with myxedema heart, which developed spontaneously in 13 and after subtotal thyroidectomy in 2. All patients but 1, a boy, were women over 40, except 4 who were over 30. The boy was 17. The heart was greatly enlarged in 12 cases and latently enlarged in 1. The enlargement was uniform for all the chambers of the heart. In some cases the transverse diameter of the heart, as determined in relation to the transverse diameter of the thorax in teleroentgenograms, was 20 cm. The maximal arterial pressure was over 160 mm. of mercury in 4

cases and between 140 and 160 mm. of mercury in 3. There was insufficiency of the heart in 4 and angina pectoris in 3. The pulsation of the contour of the heart was diminished in all cases in which roentgenoscopic observations were performed. The electrocardiogram was changed in all cases. The most typical electrocardiographic changes were flattening of the P wave, flattening or inversion of the T wave, especially in the first and second leads, and low voltage of the QRS complex in the three standard leads. Elongation of the PR interval and widening of the QRS complex were rarely observed. There were a case of auricular extrasystole and another case of complete arrhythmia. After thyroid therapy the size of the heart diminished in all cases, except when the enlargement was due to heart disease. The arterial pressure diminished in the majority of cases. The electrocardiogram gradually became normal in all cases in a given time, which varied. Favorable changes were evident after four to eight weeks. In some cases the electrical axis changed from normal to deviated or the reverse. In a case of moderate hypertension and moderate enlargement of the heart, extrasystolic arrhythmia disappeared. The electrocardiogram had a substantial favorable change. The transverse diameter diminished 1.3 cm., without reaching, however, the normal size. In a case in which the changes of the electrocardiogram were typical and the heart was of normal size the electrocardiogram became normal after thyroid therapy and the transverse diameter of the heart diminished 1.5 cm. The size of the heart did not change in a case of severe hypertension and heart disease of arterial origin. In a case of angina pectoris the anginal symptoms disappeared during thyroid therapy and reappeared because of insufficient treatment. In 2 cases of typical insufficiency of myxedema heart the electrocardiograms became normal and the symptoms rapidly improved after the administration of thyroid therapy. In 1 there were anginal symptoms for the first time in the course of the treatment. Treatment was discontinued for some time and then was reestablished with tolerable doses. The symptoms of congestive cardiac insufficiency in 2 cases in which thyroidectomy had been done were controlled by thyroid therapy.

Münchener medizinische Wochenschrift, Munich**88:641-668 (June 6) 1941**

- Use of Bacteriophages in Combating Dysentery. G. Seiffert.—p. 641.
*Statistics on Kruse-Sonne (E) Dysentery: The Infectious Intestinal Disease Most Prevalent in Germany. K. Roelcke and Maria Neuberger.—p. 643.
Surgical Treatment of Visual Disturbances in Cerebral Tumors. W. Sörgo.—p. 646.
Population and Health Policies in Germany. J. Krug.—p. 651.
Question of Expelling Mucous Secretion from Bronchi. H. Weber.—p. 656.

Statistics on Kruse-Sonne (E) Dysentery.—Roelcke and Neuberger maintain that Kruse-Sonne dysentery has shown a considerable increase in Germany during the last ten years, and they present statistical data of the Heidelberg medical laboratory to prove it. This condition is not sufficiently recognized, in spite of its increase, because it may present the aspects not only of dysentery but of enteritis. They present a table which lists 825 cases in which a pathogenic intestinal micro-organism was detected at the Heidelberg laboratory between 1932 and 1940. It is noteworthy that during these nine years the Shiga-Kruse bacillus was never detected, whereas the cases of Kruse-Sonne dysentery amounted to 462, or 56 per cent, of the total number. If one looks at the figures for the different years, a rising tendency becomes apparent. Kruse-Sonne dysentery occurs not only in individual patients but in groups, and if the ages of the patients are considered it becomes apparent that the disease is most frequent in children under 10 years of age. A curve indicating the seasonal distribution discloses the highest incidence in June, July, August and September. The regional distributions suggests that the geologic character of the land may play a part. Investigating the figures on intestinal infections for all of Germany, the authors found that the incidence of Kruse-Sonne dysentery was only slightly surpassed by that of paratyphoid. Whereas cases of paratyphoid B amounted to 31.1 per cent of the total intestinal infections, cases of Kruse-Sonne dysentery amounted to 30.8 per cent. The Kruse-Sonne bacillus accounts for over 85 per cent of all cases of dysentery in Germany; the Shiga-Kruse bacillus occurs rarely. It is probable

that the incidence of Kruse-Sonne dysentery is much greater than the aforementioned figures indicate, because the clinical picture produced by this bacillus is often so mild that medical aid is not requested or that bacterial examination is dispensed with.

*Results of Intrabronchial Injection of Moljodol in Chronic Empyema Patients. K. Yokota.—p. 557.

*Rosenstein's Mesenteric Pressure Pain Symptom and Its Surgical Significance. M. Matsuda.—p. 574.

Bronchial Picture in Chronic Empyema.—Yokota reports the results of his study of bronchograms of 15 patients with chronic empyema and of fistulograms in 2 children. The contrast medium employed was 40 per cent moljodol (an iodized oil) injected by the supraglottic method; in children with bronchial fistula the injection was accomplished by means of a syringe and a catheter. The three factors responsible for bronchial changes in chronic pyothorax were found to be (1) pressure on the affected side from accumulated pus, (2) scarred fibrotic changes of the alveolar parenchyma on the pleural induration and (3) contraction as a result of the pulmonary tuberculosis demonstrable in practically all cases of chronic pleural suppuration. In cases of partially involved chronic pyothorax the typical changes of the bronchi were seen in the middle and upper lobes of the right lung and the lower lobe of the left lung but never in the upper lobes on the two sides simultaneously. In total pyothorax, on the other hand, all lobes may be involved. In 4 instances the presence of a tuberculous cavity was demonstrated. Three of 4 patients in whom tuberculous bronchial changes were demonstrable in all lobes of the lungs died after extrapleural thoracoplasty, while 2 patients with no evidence of tuberculous changes of the bronchi went on to complete recovery. From these observations the author concludes that the prognosis of thoracoplasty can be predicted from the character of bronchograms. Fistula was demonstrated and the bronchi leading to the fistula showed remarkable changes, in 7 cases. These data were obtained by means of fistulography, which is also a valuable diagnostic aid in the surgery of diseases of the chest.

Rosenstein Syndrome and Movable Cecum.—Rosenstein (1920) proposed that the syndrome of mesenteric pressure pain is a simple differential diagnostic sign of appendicitis, and Torikata (1924) concluded that the Rosenstein-Inversus syndrome, which is the disappearance of ileocecal pressure pain present in the recumbent position on lying on the left side, is the pathognomonic sign of movable cecum (cecum mobile). The Rosenstein syndrome is due essentially to the pain arising from the elevation of the lateral peritoneal membrane from the retroperitoneal tissue; the presence of this syndrome in the absence of any signs of acute inflammation of the peritoneal cavity is diagnostic of movable cecum. All signs of mobile cecum may be removed by simple resection of the vermiform appendix. In all cases of movable cecum with a positive Rosenstein syndrome, the pericolic membranous tissue must be resected and the cecum must be fixed to the ascending colon; failure to carry out this procedure leads to chronic persistence of the syndrome.

*Experimental, Histopathologic and Clinical Studies on the Therapeutic Effect of Thymophogen on Tuberculosis. K. Ikeda.—p. 303.

Thymophogen in Tuberculosis.—Ikeda reports his observations on the therapeutic effect of sodium mono-4-chlorothymylphosphate (thymophogen) in tuberculosis. This drug was first used in 1930, when Ayukawa tested its bactericidal properties on *Mycobacterium tuberculosis* and found it to be efficacious because of the liberation of tetrachlorothymol in the tissue resulting from the hydrolytic action of the phosphoric acid enzymes. In animal experiments, using rabbits, the author injected 0.2 mg. of tubercle bacilli suspended in 1 cc. of saline solution either intravenously or directly into the parenchyma of the lung, simultaneously administering the test drug in doses varying from 0.04 to 0.4 Gm. as a 4 per cent solution. The

injections were made every other day for a total of one hundred and sixty days. On the basis of both clinical and pathologic observations the author noted that the animals receiving injections of the drug, as compared with the control animals, gave evidence of satisfactory therapeutic effects of the drug on the disease. In contrast to the control group, the treated animals showed a greater degree of fibrosis and calcification of the tubercles in the lungs. Furthermore, the author tested the phagocytic activities of the reticuloendothelial cells, with special reference to the alveolar macrophages (called pneumocytes by Shimomura) and found that these protective elements of the body were more active in the animals with experimental tuberculosis under treatment with the test drug than they were in the control animals. As a final phase of investigation, the effect of the test drug in cases of human tuberculosis was studied. For this purpose, the author selected 30 tuberculous patients with active disease and gave intravenous injections of the drug in doses varying from 0.2 to 1 Gm. at two day intervals, for a total number varying from thirty to ninety-eight injections. Of the total number of patients so treated, 14 showed definite signs of improvement due to the drug while the remainder appeared to be unaffected.

*Leprosy in Canton, China: A Survey. S. Rai.—p. 1133.

Leprosy in Canton.—While he was serving on the quarantine service, Rai made a survey of leprosy among the inhabitants of Canton. It has been estimated that nearly one million lepers, or approximately one third of the total number of lepers in the world, are found in China, where they are especially numerous in the province of Canton. Of the 52,000 inhabitants who came to the attention of the author, 84 (1.6 per cent) were found to show various symptoms of leprosy. Males predominated (55) over females (29); the oldest patient was 71 years and the youngest 5 years, the occurrence of the disease being most frequent in patients of the ages between 11 and 40. Of the commonly recognized clinical types, the distribution was as follows: anesthetic type 50 cases, nodular type 22 cases and macular type 12 cases. The incidence of alopecia leprosa was extremely low. There is no specific remedy in the ancient Chinese pharmacopeia. The author investigated the available therapeutic management of leprosy among the local practitioners of medicine and reports that in this field competent physicians are extremely rare. He expresses the opinion that a more adequate control and treatment of the disease is urgent if the number of lepers is to be reduced to the minimal level. He advocates institutional care of all patients with active leprosy.

*A Live Plague Vaccine and the Results. L. Otten.—p. 61.

Live Plague Vaccine.—Otten, of the Pasteur Institute at Bandoeng, Java, who has studied plague immunization for more than ten years, says that opinions are divided about the potency of dead plague vaccines. After he had become convinced that it is impossible to stimulate satisfactory immunity in rats and guinea pigs by means of killed bacilli he decided to use a live vaccine. His investigations in this direction were hastened by the chance discovery of a strain that had lost its virulence completely. The favorable results obtained with a live, avirulent variant of the plague strain "Tjiwidej" in the immunization of rats and guinea pigs induced him to investigate to what extent these might also be obtained in man. He demonstrates that, according to the technic he used, the finding of avirulent variants of plague strains involves no particular difficulties and that neither the production nor the application of live plague vaccine involves unpleasant surprises or dangers. During the five years from 1935 to 1939 he employed the live vaccine in a vaccination campaign which extended to more than two and a half million subjects and in which nearly ten million vaccinations or revaccinations were done without harmful consequences to the health or life of the population.

Book Notices

Infantile Paralysis: Anterior Poliomyelitis. By Philip Lewin, M.D., F.A.C.S., Associate Professor of Bone and Joint Surgery, Northwestern University Medical School, Chicago. Cloth. Price, \$8. Pp. 372, with 166 illustrations by Harold Laufman, M.D., Philadelphia & London: W. B. Saunders Company, 1941.

This book is well sprinkled with illustrations. There is a large bibliography and a good cross index. It contains chapters on the history of the disease, port of entry and physical examination. The greater part of the book has to do with care of the patient. As with any book, it represents the opinions of the authors only at the moment it was written, and these are often outdated by the time publication occurs. Some weight is given to laboratory data to support the thesis that the port of entry might be considered as of gastrointestinal origin, but little space is given to clinical evidence. The latter is the only clear-cut evidence that has consistently pointed to the fact that the disease could not possibly enter by way of the nose, despite the massive amount of laboratory work done during the last thirty years to prove this thesis. It would seem that more of this type of evidence should be mentioned.

From a physician's point of view the work is a good reference textbook. Its illustrations are easy to comprehend. One might disagree with the statement that there is such a thing as "the time relationships between the systemic phase, the period of passage through the meningeal blood vessels, the lymphatics, and the choroid plexus to the cord. . . ." Perhaps the author did not mean to imply a systemic disease with spread through the meningeal vessels, and so on. One might also disagree with the statement "Bulbar paralysis is only occasionally associated with paralysis of the spinal nerves and muscles." Nor can one agree with the statement that it is much better to keep a patient at home than to send him to a hospital. One might also disagree with the conclusion that convalescent serum should be used in large amounts intravenously and in small amounts intraspinaly. The bald statement that the spinal fluid is an index of progress is only roughly true. Notwithstanding these disagreements and minor errors, the book is complete and contains a valuable appendix and all the practical information that one need know about infantile paralysis. It can be recommended. The remarks on the hypothetic means of dissemination, on the epidemiology and on predisposing factors are interesting. The author is amenable to reasoning. In fact, he states that it is quite possible that treatment might be begun a little bit earlier than heretofore recommended by most orthopedic surgeons.

Operative Surgery Including Anesthesia, Pre- and Postoperative Treatment, Principles of Surgical Technic, Blood Transfusion and Abdominal Surgery. Edited by Frederic W. Bancroft, A.B., M.D., F.A.C.S., Associate Clinical Professor of Surgery, Columbia University, New York. Cloth. Price, \$10. Pp. 1,102, with illustrations. New York & London: D Appleton-Century Company, Incorporated, 1941.

The production of a new work in surgery is an event greeted with critical interest. The mere delineation of a number of operations is not ordinarily sufficient to warrant publication. In many ways this volume justifies itself because of the fresh points of view. A number of distinguished surgeons have collaborated in presenting the various phases of abdominal surgery. The book begins with a large section on anesthesia which is actually the work of six men. The advantages of such a method are obvious, since each man writes about the particular type of anesthetic or other agent in which he is most interested. The disadvantages can be overcome only by firm editorial guidance, so that contradictions and repetitions are eliminated. Furthermore, such an arrangement may permit important omissions. It is questionable whether or not the field of anesthesia is now so complex that one or two skilled and well trained physician anesthesiologists could not present an adequate picture. A more unified presentation would be preferable. Nowhere in the section are the fundamental principles of anesthesia outlined. The physical signs and manifestations of the various planes of anesthesia are not presented or described by any of the six contributors, so that the entire physiologic basis of anesthesiology is omitted.

The division of the section into preanesthetic medication, inhalation, rectal, intravenous, spinal and regional anesthesia is artificial, since no anesthetic is complete without the first, and the latter are frequently combined.

Other sections are concerned with preoperative and postoperative care, blood transfusion, technic, surgery of the mouth, esophagus, peritoneum and the various intra-abdominal organs. Just how surgery of the mouth is related to abdominal surgery is not made clear, and with slightly less objection surgery of the esophagus may be placed in the same category.

The contributions on these subjects, however, are generally satisfactory. In fact, much excellent information may be found on every page. This volume seems to be merely the binding together of a series of monographs. Often tabular material and other minutiae are included by some of the authors which for textbook purpose could well be further digested and condensed. Apparently insufficient effort was made to confine the contributors to their particular fields. Repetitions are numerous and needless. Perhaps fewer collaborators would have prevented some of this waste. For example, while it is conceded that the Ochsner operation for suprahepatic abscess is useful, it need not be described in detail (with the same illustrations) three separate times (pp. 499, 792, 958). Another example is the repeated description of the McBurney incision. Such repetitions probably contribute much more to the cost than to the value of the book.

Surgeons can find much of interest in this book, but unification and elimination of nonessentials would render it more practical.

Die Störungen der Blutgerinnung beim Kinde mit besonderer Berücksichtigung des K-Vitamins und der Neugeborenenpathologie. Von Professor Dr. G. Fanconi, Direktor der Universitätskinderklinik Zürich Boards. Price, 7.20 marks. Pp. 160, with 21 illustrations. Leipzig: Georg Thieme, 1941.

The recent discovery of vitamin K and the impetus it has given to a more intensive study of the problems of blood coagulation has resulted in the publication of concise monographs both in this country and abroad. This condensed presentation first reviews and summarizes the current views on blood coagulation and the methods available for the quantitative study of the various factors. The discussion of the five main factors concerned with disturbed blood coagulability is terse except for hypoprothrombinemia, which receives the major emphasis. The author attempts to evaluate the part that calcium, fibrinogen, thrombokinase (thromboplastin), heparin and prothrombin play in bleeding states in children. Fanconi frankly states that he has never seen a case of bleeding on the basis of insufficiency of fibrinogen and only 1 questionable case in which decrease in calcium may have been a factor. The role of insufficiency of thrombokinase (thromboplastin) is concerned mainly with hemophilia, and the author critically reviews the evidence for and against the current theories. The part that heparin plays in the hemostatic mechanism is next evaluated, and Quick's and Whipple's views are mainly quoted. The subject of hypoprothrombinemia, however, receives the major emphasis in the monograph and is discussed under four main subgroups: (1) hypoprothrombinemia in sprue and celiac disease, (2) hypoprothrombinemia in liver disease, (3) hypoprothrombinemia in the newborn and (4) hypoprothrombinemia of unknown etiology. In the discussion on hemorrhage during the newborn period the author introduces a philosophical conception of extrauterine adaptation or transformation destruction to explain the dissociation of a number of vital functions which occur immediately or during the first four days of life. Whether such a speculative attempt is justified with such meager facts is questioned. The author concludes the monograph with a short summary which is rather generalized, and at the end all of the 47 cases cited are listed under their respective bleeding difficulties. The discussion is well documented with current references, and case reports are freely offered with separate case analyses. The work is concise and well written but, like all monographs on this subject, because of the paucity of conclusive data, leaves many questions unanswered. The work is stimulating and should interest those concerned clinically with the problems of disturbed blood coagulation in children.

Your Personality—Introvert or Extravert? By Virginia Case. Cloth. Price, \$2.50. Pp. 277. New York: Macmillan Company, 1941.

This book represents another of the seemingly endless stream of theoretical psychologic studies that are being written and published for popular consumption. Many unsuccessful or useless attempts have been made to classify people according to type, both physical and psychologic. Although it is true that the descriptive nomenclature now employed to depict certain attitudes in human personality is extremely inadequate, further attempts to describe and clarify these unfortunate classifications only leads to more confusion. The only classifications that can possibly be of any value must be based on a dynamic analysis of the total personality of the individual and not on a descriptive classification of groups. The general public is susceptible to this sort of schematic presentation, and countless pseudo-scientific publications reach the shelves of our book stores and are accepted as valuable contributions to a common understanding of human personality. In addition to the general theme of classification of all peoples into two types, introverts and extroverts, the author introduces apollonian types, archetypes, chemical types, physical types (according to Kretschmer), cycloid types, gregarious types, leptosome types, moody types, flexible types, positive types, schizoid types and Dionysian types as well as types of writers and types of intellects. There is little in this book that is of any value either to the scientific psychologist or to the layman.

Textbook of Bacteriology. By Edwin O. Jordan, Ph.D., and William Burrows, Ph.D., Assistant Professor of Bacteriology, University of Chicago. Thirteenth edition. Cloth. Price, \$6. Pp. 731, with 170 illustrations. Philadelphia & London: W. B. Saunders Company, 1941.

Thirty-three years ago, when the first edition of this book was reviewed, THE JOURNAL said that it was destined to occupy a large field of great usefulness. The prophecy has been fulfilled. Long ago the book came to be widely used by medical schools and their graduates and others. Bacteriology is a comparatively young and vigorous science, which is still growing, as evidenced by the numerous editions and the gradual increase in size of the book. After the original author passed away, the twelfth edition was revised by Dr. Burrows, assistant professor of bacteriology at the University of Chicago, where the book originated. Now the cumulative effects through the decades of slowly moving developmental processes indicate the desirability of completely rewriting the book. The present edition has been constructed on a somewhat different basis than its predecessors. The chapters devoted to the highly specialized applied fields, such as soil, industry and dairy bacteriology, have been eliminated and parts of them incorporated together with new material into a chapter on bacterial physiology. A separate chapter has been written on the mechanisms operative in the transmission of infection. The fundamental principles of epidemiology have been developed through consideration of the interaction of host and parasite populations. The subjects of water and milk are considered in terms of the transmission of disease. The subject of immunity is covered in two chapters, one devoted to antigens, antibodies and the chemical basis of immunologic specificity, the other to specific resistance of infectious disease discussed in terms of humeral and cellular immunity and hypersensitivity. The many chapters devoted to the various bacteria include much new material. Consideration of the filtrable viruses has been expanded to two chapters; the first is a general consideration of the properties of viruses, and the second is given over to the virus diseases of man. This edition, like previous ones, has the references to literature at the bottom of the pages rather than in one large bibliography in the back of the book. The index generally is the same, except that now there is no separate index of authors. There is less space between the type on the page than in some previous editions. The style trends more toward technical expressions, making it perhaps a little less clear and crisp. The familiar dark blue of the binding has been changed to dark brown. The price is just double that of the original edition published in 1908, although the number of pages differs by only a hundred and seventy-four. The present author and the publishers have done well indeed in carrying on the tradition of this widely used book.

Martin Luthers Umwelt, Charakter und Psychose sowie die Bedeutung dieser Faktoren für seine Entwicklung und Lehre: Eine historisch-psychiatrische Studie. Von Dr. Med. Paul J. Reiter, Chefarzt der Psychopathenanstalt in Herstedvester. II: Luthers Persönlichkeit. Seelenleben und Krankheitsverlauf. Paper. Price, 35 Danish kroner. Pp. 633, with 17 illustrations. Copenhagen: Ejnar Munksgaard, 1941.

This is a pathography but as unlike the ordinary run of pathographic description as is a newspaper health column compared with a well controlled clinical experiment. After four hundred years Luther's life and character are still subjects of lively controversy, and an analysis of his work and personality in psychopathologic terms calls not only for erudition but in perhaps larger measure for courage and tact. The author, well known in the psychiatric field, possesses all three qualifications. It takes tact to discuss from the point of view of psychosis or psychoneurosis the inner conflicts and outer struggles of an idol worshiped by hundreds of millions and to maintain an objective approach, indulging neither in condemnation nor in justification. It takes both tact and courage to argue the delicate question whether or not excessive masturbation, intemperance or a possible syphilitic infection might have influenced Luther's life and teaching. By applying a strictly clinical method of dealing with the source material, Reiter has skillfully avoided the pitfalls of partisanship and sensationalism. After extensive differential diagnostic consideration, the final verdict is offered that the great reformer suffered from a manic-depressive condition. The possibilities of a neurasthenia or a schizophrenic or epileptic psychosis are discarded. The book is a mine of psychiatric knowledge with illuminating discussions on specific syndromes and general diagnostic issues, particularly those of temper, character and total personality. The literature is ably covered, the index is neatly arranged and the beautiful illustrations are well chosen. The volume is recommended to psychiatrists as instructive and stimulating reading.

Essentials of Pharmacology and Materia Medica for Nurses. By Albert J. Gilbert M.D., Instructor of Pharmacology, Aultman School of Nursing, Canton, Ohio, and Selma Moody, R.N., Instructor in Nursing Arts, The Presbyterian Hospital of the City of Chicago. Cloth. Price, \$2.25. Pp. 251, with 15 illustrations. St. Louis: C. V. Mosby Company, 1941.

This little book is a placebo: something to soothe the student nurse and entirely without stimulating properties. It is harmless to the extent that it will do no active damage but potentially harmful, for it may leave the baneful impression that it contains the subject matter of a course in pharmacology and materia medica. The course in nursing allocates about thirty hours to this subject. It is a short period, and too much should not be attempted. However, nurses have opportunity to see drugs and their effects, which should be the equivalent of added hours. Student nurses are graduates of high schools and have been accustomed to educational methods. They should be able to assimilate much more pharmacology and materia medica than is presented in this book of "essentials." The object stated is to present the facts and theories of the subject in a lucid, concise form adapted to the limited time for the course in many nursing schools. The book is clear in statement but too dogmatic, as short statements are apt to be. It would seem better pedagogy to include more information, which would save the student's time in looking for it elsewhere and leave to the judgment of the teacher the amount and range demanded.

A Practical Manual of Diseases of the Chest. By Maurice Davidson, M.A., M.D., F.R.C.P., Physician to the Brompton Hospital for Consumption and Diseases of the Chest, London. Second edition. Cloth. Price, \$13.50. Pp. 575, with 200 illustrations. New York & London: Oxford University Press, 1941.

The purpose of this volume is to make available to the internist or general practitioner for the purposes of reference a textbook on diseases of the chest but not including the heart. As the author states, "The exhaustive treatise, of vast dimensions, is too unwieldy to serve the busy practitioner; the small manual, of which there are several excellent examples, can make no pretence to be a standard of reference for those whose studies call for deeper research into the literature and pathology of the conditions dealt with. The present volume represents an attempt to supply a *via media* between these two paths." This book accomplishes the purpose fairly well. Appended to the various discussions are references dealing more exhaustively

with the various subjects discussed. The salient features of the usually encountered diseases are adequately covered and beautifully illustrated by numerous roentgenograms. Since the volume is intended primarily for physicians interested in the general field of medicine, one would welcome more extensive discussion of differential diagnosis. Particular attention is devoted to treatment, stressing particularly the practical aspects. The statement that, aside from the emergency use of bleeding for venous distention and cyanosis, "we are of the opinion that an initial venesection (in the first two days) and removal of at least 10 ounces of blood in a full blooded patient with pneumonia is a good practice and one likely to lessen the tendency to cyanosis and undue respiratory embarrassment" would not find general agreement in this country. Proprietary preparations are given undue prominence. The rapidity with which our knowledge has progressed with regard to chemotherapy is shown by the fact that the section on drug treatment of pneumonia is already somewhat obsolete and incomplete.

Untersuchungen über die Tetryl-, Tetryl- und Knallquecksilber-vergiftungen bei den Arbeitern der Munitionsfabriken Finnlands. Von Leo Noro. *Acta medica Scandinavica. Supplementum CXX.* Paper. Pp. 95, with 7 illustrations. Helsingfors: Mercators Tryckeri, 1941.

Five years ago any publication from Finland on the toxic properties of then little known complex munition chemicals would have commanded scant attention. Today, contrariwise, this publication is of immediate significance for all physicians, chemists and engineers concerned with munitions. With arsenals springing up all over the country it becomes conceivable that "tetryl poisoning" may become as close to all physicians as the omnipresent carbon monoxide poisoning. Written in the summer and fall of 1940 by a battalion physician just after the Finnish-Soviet war, this small publication (in German) presents his observations of the damaging effect on munition workers of numerous aromatic nitro compounds, chiefly tetryl and tetryl, and the substance better known in this country as mercury fulminate. In addition to his own observations from laboratory, clinical and necropsy material, the author furnishes critical literature appraisals and an extensive literature compilation. Noro's results are not in keeping with the observations of other scientific workers in Europe on other war materials that hours of labor are outstandingly important to the incidence of industrial poisoning, but instead this work attaches prime significance to individual susceptibility calling for especial care in the selection of this class of munition workers. No less, Noro repeatedly stresses the significance of the hygiene of work places as an essence of national defense. Implied throughout the book is the concept that the immediate havoc of war is not limited to those directly attacked but may include men and women far from battle fronts and bombed areas who may be engaged in the manufacture or handling of explosive substances.

Vision: A Study of Its Basis. By S. Howard Bartley. With an Historical Perspective. By Edwin G. Boring. Cloth. Price, \$3.50. Pp. 350, with 78 illustrations. New York: D. Van Nostrand Company, Inc., 1941.

This work is admittedly a handbook on the subject of vision. As such it is reasonably comprehensive, although in some few instances clarity is sacrificed for the sake of brevity. The book is well documented, the references including most of the recent works that are covered in the discussion. The author approaches the entire subject in an orderly and logical fashion, considering first the fundamentals of physiologic optics with particular reference to the entoptic phenomena in relation to their effect on the neurophysiology of the perceptive units. From this the author proceeds to the topic of neurohistology of the perceptive elements and finally to the neurophysiology of all the elements involved in the visual pathway. It is to the last named subject that the author devotes most of his discussion with chapters on repeated stimulation (flicker), perception of movement, adaptation phenomena, neural interaction and contour. Discussion of the optic pathways and the cortical response are followed by an excellent conclusion in which the author points out the road that has already been traveled in attempting to elucidate this subject and what remains to be done. Unfortunately the author has considered the realm of color vision to be outside the scope of this book and has therefore left out any reference to this phase of the subject.

Die Methoden der Fermentforschung. Unter Mitarbeit von Fachge-nossen. Herausgegeben von Prof. Dr. Eugen Bamann und Prof. Dr. Karl Myrbäck. Lieferung 8. Paper. Price, 34.50 marks. Pp. 2589-3047, with 86 illustrations. Leipzig: Georg Thieme, 1941.

This is a continuation and the completion of the text of a large work on methods of investigating enzymes. The bibliography and index still remain to be published. The contents of the present volume begin with page 2589. The general subject matter includes: Aspartase by Jorma Erkama and A. I. Virtanen, Helsinki. Peroxydase and catalase by Karl Zeile, Göttingen. Hydrogenase by M. Stephenson and D. D. Woods, Cambridge, England. Reducing substances of unknown mechanism: the thiol disulfide system by Theodor Bersin, Marburg. ascorbic acid by Peter Holtz, Rostock, and quinone bodies by F. Lynen, Munich. Assimilation: carbon dioxide by M. Steiner, Göttingen, and Horst Engel, Münster, nitrogen by A. Virtanen and Tauno Laine, Helsinki. Antienzymes by J. B. Sumner, Ithaca, N. Y. Ferment models by Wolfgang Langenbeck, Dresden. The enzymes of the industries: brewing by Hugo Haehn, Berlin; fat by Emil Hoyer, Rostock; malt extract by S. Preiz, Breslau; baking by H. Thaler, Munich. The distribution of authorship gives an international tone to the work, clearly of a special nature but valuable to research workers in many phases of biology. Since fermentation enters into so many phases of the kinetics of life, it is practically synonymous with life itself. As a type of the detailed inclusiveness of the work, we may select the first subject, aspartase. The treatment of this includes the naming of the enzyme, its occurrence in micro-organisms, plant and animal tissues; its preparation, purification, experiments on its action, and the products formed; the substrate; specificity; isolation and determination of the reaction products; kinetics of action; obtainability; aspartase as a reagent in the estimation of aspartic acid. This work has a place in every laboratory interested in fermentation. It should be more valuable when the index and references are published.

Essays on the Applied Physiology of the Nose. By Arthur W. Proetz, A.B., M.D., Professor of Clinical Otolaryngology in the Washington University School of Medicine, St. Louis. Cloth. Price, \$7. Pp. 395, with 91 illustrations. St. Louis: Annals Publishing Company, 1941.

There is no doubt that any contribution which is intended to correlate our past and present knowledge of the physiology of the nose and sinuses is a welcome addition to a trend which has brought this field to the forefront. This monograph should serve as a challenge to workers who are interested in the field of nasal physiology to produce a definitive work. The author himself has this feeling, for in his introduction he regards his own preparation for the basic field as inadequate and offers instead a "lifetime of clinical experience" and "an absorbing interest." The author draws a corollary between the progress made by the studies in nasal pathology; he felt that if he wanted to read a specialized book on nasal physiology he would have to write it himself. The book, of twenty-one chapters, gives a sketchy outline of some of the historical contributions to this special field. On the basis of what is now known regarding ciliary action and its response to various agents, Proetz also gives an applied physiology. The structure of the nose and its relationship to function, olfaction, air currents and pressure, humidification, the mucosa as a defensive structure, vascular, lymphatic and neural reactions, are all discussed in a simple terse style based on the author's own contributions and those contained in the literature. An attempt is made with a modicum of success to correlate the commonly employed types of nasal surgery and medical treatment to the basic physiology. A universal appreciation of this principle could have a far reaching effect on the general tendency for indiscriminate intranasal medical and surgical therapy. Proetz's pioneering effort presages a constructive era in rhinology.

The Conquest of Bacteria from 606 to 693. By F. Sherwood Taylor, Ph.D., M.A., B.Sc. Second edition. Cloth. Price, 6s. Pp. 144. London: Seeker & Warburg, 1940.

This is a record of the historical development of the measures by which the conquest of bacteria has thus far been achieved. Intended for the layman, it is to be commended for its scientific soundness and interesting style. It achieves its purpose without resort to melodramatic distortions. Since the volume was written in England by an Englishman during the present war, American contributions to modern chemotherapy have been

almost entirely ignored. But an otherwise excellent account of sulfanilamide and sulfapyridine does not even refer to the work of Perrin H. Long or of any other American investigator. The author also creates the impression that the new chemotherapy was not warmly welcomed in America because of the "elixir of sulfanilamide" incident, which was certainly not the case. With respect to sulfapyridine in pneumonia, the author expresses the pious hope (in 1940) "that the new treatment will completely establish itself within a year or so" in the United States.

Abdominal Surgery of Infancy and Childhood. By William E. Ladd, M.D., F.A.C.S., William E. Ladd Professor of Child Surgery at Harvard Medical School, Boston, and Robert E. Gross, M.D., Associate in Surgery, the Harvard Medical School. Cloth. Price, \$10. Pp. 455, with 268 illustrations. Philadelphia & London: W. B. Saunders Company, 1941.

Without doubt this is a predestined classic in its field. Abdominal surgery of children has long been regarded as difficult but, in spite of remarkable results, has been retarded by an excessive operative mortality. So much satisfaction can be attained by various surgical procedures that special attention to improve operative mortality is more than warranted. In this endeavor the senior author has long been regarded as a leader. An excellent chapter on congenital pyloric stenosis is first in the book. The various infantile and congenital disorders of the alimentary tract and its auxiliaries follow. The volume concludes with a fairly complete discussion of diseases of the male and female urogenital tracts. However, malformations associated with hypospadias are not included. Many fine photographs and drawings are included which represent chiefly the experiences of the authors and the techniques they use. Statistical data and frank statements concerning the actual risk and value of various operations are an important feature. Any active abdominal surgeon should be able to perform many of the procedures described, since he is likely to possess the consummate skill and speed in operating demanded by surgery in infants.

Following a Doctor's Satchel: An M.D. Talks from Fifty Years Experience. By A. O. Scarborough, M.D. Cloth. Price, \$1. Pp. 96, with portrait. Grand Rapids: Wm. B. Eerdmans Publishing Co., 1941.

Unlike most books written by venerable physicians, this one is not an autobiography. The author is still practicing medicine in a small city in Texas at 80 years of age and he simply wants to pass on the wisdom he has acquired during a long career. His advice is deeply rooted in religious principles. In his short philosophic essays he writes about love of country, paternal love, love of money, pride of ancestry, love of nature, anger, fear, sympathy. He has definite ideas about some more modern problems also. The attempted inroads of politics into the practice of medicine he has found to be very undesirable. He believes that the rise of the cults today can be explained by the prophecies in the Bible, which told us that the time would come when people would not endure sound doctrines but would run off after fables. Younger people might spend an hour, which is about all it takes to read the book, with the kindly and keen octogenarian. Interest grows as the pages go by. The editor incidentally overlooked some punctuation points, capital letters and long sentences in the opening pages of the book.

The Health and Efficiency of Munition Workers. By H. M. Vernon, M.A., M.D. Cloth. Price, \$2.50. Pp. 138, with 15 illustrations. New York & London: Oxford University Press, 1940.

In this small volume the author gives a brief exposition of England's experience with hours of work, work spells and rest pauses, shift systems, sickness and absenteeism, accidents and injuries, ventilation, heating and lighting of factories, and welfare and labor management in relation to munitions output in the World War and the early days of the present war. Throughout the volume the importance of maintaining the health of the munition workers is emphasized, although he gives no specific methods. He presents a good case, however, for certain limits of productive effort, at which best results in output can be obtained without impairment of health. Appearing on the threshold of our own national defense effort, this book has value to industrial physicians, but more particularly to industrial management.

Sorting Tests in Relation to Drug Therapy in Schizophrenia. By Joseph Zubin, Ph.D., Associate Research Psychologist, New York State Psychiatric Institute, New York, and Jane Thompson, Ph.D., Psychological Assistant, New York State Psychiatric Institute. Paper. Pp. 23. New York, 1941.

This small monograph was undertaken to check the findings of another author regarding a supposed relationship between patients' performances before and after insulin and metrazol shock therapy. The sorting tests were purely psychologic with a statistical analysis. The tests used were the Weigl Color Form, the Vigotsky and the BRL sorting. One hundred and fourteen patients were studied. The conclusions were that the sorting tests showed the existence of a definite relationship between patients' performances before and after shock therapy. There is a good bibliography. This publication is recommended to all psychologists.

Standard Radiographic Positions. By Nancy Davies, M.S.R., Senior Radiographer, Royal Surrey County Hospital, Guildford, and Ursel Isenburt, M.S.R., Radiographer to the Charterhouse Rheumatism Clinic, London. Cloth. Price, \$2. Pp. 136, with 103 illustrations. Baltimore: William Wood & Company, 1941.

This is a little handbook on radiographic positioning, of such size as to fit into the pocket of a coat or gown and intended to serve as a ready reference book for standard radiographic positions. For details of technic of special x-ray examinations the reader is referred to more elaborate books. The illustrations are diagrammatic, only the main structures and outlines being given. In view of the needs of these war days, considerable space is devoted to positions required in the x-ray localization of foreign bodies. In perusing this work one finds little to criticize. It is not a pretentious publication, but it serves well for the purpose intended and should be valuable for radiographic technicians.

Die tägliche gynäkologische Sprechstunde. Von Dr. M. Rodecurt. Cloth. Price, 10.50 marks. Pp. 308, with 3 illustrations. Leipzig: Georg Thieme, 1941.

This book, which is devoted to office gynecology, has nineteen chapters including those dealing with infections of the genitalia, malpositions of the uterus, abnormal uterine bleeding, endocrinology, sterility, habitual abortion, pregnancy, diseases of the breasts, backache, rheumatic-neuritic-neuralgic-vegetative symptom complex, the menopause, cosmetics and sexualia. Some of the chapters are disproportionately large. The one dealing with *Trichomonas* occupies forty pages, or one seventh of the book, whereas only eight pages are devoted to gonorrhea. There are only three illustrations in the entire book, two of which depict *Trichomonas* and the third shows the Knorr instrument, which is used for applying silver nitrate to the bladder in cases of urinary incontinence. The book is well written, but it loses a great deal of its value because of the almost complete lack of illustrations, which are essential for the instruction the author attempts to give.

Necropsy: A Guide for Students of Anatomic Pathology. By Bela Halpert, M.D., Assistant Professor of Pathology and Bacteriology, Louisiana State University School of Medicine, New Orleans. Cloth. Price, \$1.50. Pp. 75. St. Louis: C. V. Mosby Company, 1941.

This brief manual, written primarily for students, describes in a systematic manner the procedure for conducting a necropsy. The anatomy of the organs and their anatomic relationships with associated structures are emphasized in twenty brief sections. No discussion of any pathologic alterations of the organs is attempted. The principles for a complete necropsy record are stated in the appendix. Two sample records including anatomic and microscopic descriptions are given as examples of a representative report. The book is entirely devoid of illustrations. The medical student and intern will find this a handy book for quick reference.

Laboratory Guide in Elementary Bacteriology. By M. S. Marshall. Fabrikoid. Price, \$1.75. Pp. 244. Philadelphia: Blakiston Company, 1941.

This little laboratory guide is designed to serve a course in elementary bacteriology. It is, however, a little astonishing to find listed the nine volume System of Bacteriology and Topley and Wilson's two volume Principles of Bacteriology and Immunity as textbooks for an elementary course. The value of this guide can be determined only under conditions of actual use and will doubtless be found satisfactory for some courses and not for others.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

NAPOLEON'S URETHRAL STRICTURE

To the Editor:—Some years ago in a paper on the history of Napoleon the assertion was made that the battle of Waterloo was lost because Napoleon, on account of a urethral stricture, could not pass his urine. Can you give such information as would lead to a corroboration of this statement?

Edward J. III, M.D., Newark, N. J.

ANSWER.—Dr. Edmund Andrews, in a paper entitled *The Diseases, Death and Autopsy of Napoleon I*, published in *THE JOURNAL*, Dec. 21, 1895, page 1081, presented evidence on which the assertion mentioned in the query may have been based. Andrews in that article quoted Field Marshal Garnett Wolseley, who was at that time (1895) head of the British army, as stating "that at the battle of Waterloo Napoleon suffered pain in riding, and that he had a table set in the open air in a suitable position for receiving dispatches and issuing orders, where he sat for hours, much of the time asleep, leaning his head on his arms." Further in Andrews' article the following sentence appears: "All this terrific labor he accomplished while suffering under a genitourinary disease which may have partly weakened his force of will." Andrews continues: "During the Russian campaign in 1812, Napoleon began to have difficulty in expelling his urine." Andrews states that there can be but little doubt that the trouble was urethral stricture with cystitis. He says that the sequence of events seems to have been (1) an attack of gonorrhea, (2) a stricture of the urethra, (3) a cystitis, (4) nephritis with a few small calculi and (5) albuminuria, dropsy of the legs, and uremic poisoning in a moderate degree.

FAMILIAL TREMOR

To the Editor:—A woman aged 54 has had intention tremor of the head and hands since childhood. Her father, one sister out of a family of eight, and several cousins have all had the same tremor, although to a lesser degree. The tremor becomes much worse under stress and strain and almost completely disappears when she is at rest. I have tried 1.200 grain (0.0003 Gm.) of scopolamine three times daily without success. One and one-half grains (0.1 Gm.) of phenobarbital at a time gives only slight relaxation and does not make her at all drowsy. Alcohol is the only drug which will give her complete, although temporary, relaxation. After she has drunk about half a cocktail her hand will become so steady that she can lift the glass without spilling any liquid. At other times she has to drink through a straw. Can you tell me of any other drug which will have a similar reaction?

Elizabeth Brakeley, M.D., Montclair, N. J.

ANSWER.—There is no drug as useful as alcohol in abolishing a familial tremor. The effect, however, is temporary and this method of therapy cannot be used in a routine manner.

Not many experiments have been made on tremors of the familial kind, but there is a large literature with regard to the effect of drugs on the tremors of parkinsonism, either of the postencephalitic or of the paralysis agitans type. Ziskind (*THE JOURNAL*, July 3, 1937, p. 20) has shown that phenobarbital tends to increase the rigidity of chronic encephalitic parkinsonism, and Friedman's work (*Bull. Los Angeles Neurol. Soc.* 5:120 [June] 1940) indicates that the same drug decreases the steadiness and increases the tremor. Scopolamine has long been recognized as a drug having the effect of releasing the rigidity of paralysis agitans but at the same time making the tremor worse either through the lessening of the rigidity or by some direct action on the nervous mechanism. Neither phenobarbital nor scopolamine would seem likely, therefore, to be of value in controlling a familial tremor.

The occurrence of tremors in animals deprived of vitamin E, as shown by Mackenzie (*Proc. Soc. Exper. Biol. & Med.* 44:95 [May] 1940), has led to the use of alpha-tocopherol in patients suffering from tremors of various types. The results, so far as known, have not been beneficial, but no published series has yet appeared in the literature. This method of treatment is worthy of further trial, although the outlook for a favorable result is not good.

A more promising field lies in the use of the belladonna alkaloids. Raef, a Bulgarian plant collector, was first to use the extract of belladonna root in 1926, and the treatment of

parkinsonism by this method was intensively studied in Italy by Panegrossi (*Policlinico [sez. prat.]* 42:46 [Jan. 14] 506, [March 18] 1935). The results were uniformly good both in Italy and in Germany. The preparation used was a white wine extract of the whole belladonna root. Later American, English and Italian belladonna root was substituted for the original Bulgarian product with equally good results. The extract is not well tolerated by the aged, the arteriosclerotic or the alcoholic. Toxic symptoms in other groups of patients are rarely seen.

From the work with belladonna root in parkinsonism, it was concluded that the therapeutic effect of the belladonna alkaloids is increased when they are given in combination, as in an extract of the root. When the purified alkaloids are extracted and put together in a tablet, the results are equally good, as shown by the work of Gayle and Pettis (*Am. J. Psychiat.* 97:1175 [March] 1941). They used a compound of atropine, scopolamine and hyoscyamine. Their report is based on the treatment of parkinsonism alone, without cases of familial tremor. The results were striking and the combined drugs were not dangerous, with ordinary precautions, to use. Riebold (*München. med. Wchnschr.* 87:1183 [Oct. 25] 1940) reports one case of familial tremor treated with the belladonna root extract, with surprisingly good results. Either the extract or the compound tablet may be tried, therefore, in this case.

EXFOLIATIVE DERMATITIS AND ALOPECIA

To the Editor:—A man aged 24 complains of complete loss of hair of the scalp and inability to sweat, except on the hands and face. He suffers extremely during the summer months and can hardly do any work. He had a skin condition two and one-half years ago, at which time his skin peeled off several times over a period of four months and during which he lost all his hair. (This sounds like an exfoliative dermatitis.) Following this he began having trouble with his sweat glands. Physical examination and laboratory tests are negative. Examination of the skin reveals the hands and face to be moist. The rest of the skin is extremely dry. What is this condition? Is there any treatment for it? Would a biopsy of the skin give any information?

M.D., South Dakota.

ANSWER.—The man probably had an exfoliative dermatitis, a symptom complex which may be due to divers causes. The history is not sufficiently informative to differentiate among these several causes. The primary or type of Wilson-Brocq exfoliates with large scales over a prolonged period and is accompanied with few constitutional symptoms. The inference is that this man's exfoliative dermatitis did not last long. The secondary type of exfoliative dermatitis appears as a complication of some preexisting eruption such as psoriasis, lichen planus or pityriasis rubra pilaris, which has been too strenuously treated or which has spread, to become universal. The history does not mention anything about a preceding eruption. Pityriasis rubra of Hebra exfoliates with fine branny scales; the skin becomes pigmented and bronzed and atrophic. This is supposedly on a tuberculous basis, but some patients who have had this dermatitis are known to have developed frank leukemia. This entity too is long lasting and would not seem from the history to have been present. One of the several members of the lymphoblastoma group—leukemia, Hodgkin's disease, lymphosarcoma and granuloma fungoides—may give rise to exfoliative dermatitis as one of their nonspecific varieties of eruption. Eventually some specific sign of their presence, such as changes in the blood or type of clinical and histologic cutaneous change, makes them recognizable with certainty. This patient would not seem to be suffering from anything in the lymphoblastoma group of diseases. Exfoliative dermatitis may be on a toxic basis, as in idiosyncrasy to one of the arsphenamines.

The complete loss of scalp hair dating from the time of the exfoliative dermatitis may be assumed to have been part of the latter process. Loss of hair and nails not uncommonly occurs with exfoliative dermatitis. It is usual, however, for the hair to regrow. The history does not mention anything with regard to other hair than on the scalp. There is a possibility that the loss of hair may be an extensive alopecia areata. In this, one would expect the hair at other sites than the scalp to be affected.

Alopecia areata is a somewhat attractive diagnosis, because in it there is supposedly present a functional imbalance or disorder of the vegetative nervous system. This seems a probability here because of the excessive sweating of the palms. Excessive sweating may be due to debilitated states and toxic processes, but in such cases it is more generalized. In hyperhidrosis due to organic nervous changes, the sites may be localized but are not apt to be symmetrical as is the fact with

this patient. Excessive perspiration of the palms and soles commonly accompanies emotional tension. Sweating may be induced by direct or pharmacologic stimulation of components of the vegetative nervous system and, contrariwise, diminished or absence of sweat secretion follows their depression.

The probability exists that the patient has some functional nervous disorder. The services of a neuropsychiatrist would be valuable. The patient should be reinvestigated to rule out some source of toxemia or endocrinal change. Can anything abnormal be found with regard to the pituitary body by roentgen ray examination? If nothing definite can be found to account for the patient's troubles, certain empirical and symptomatic agents may be useful.

The patient should be withdrawn from an environment and situations which increase emotional tension. Certain drugs may be helpful, such as the use of antispasmodics. Thyroid may be cautiously tried. For excessive sweating of the palms and soles, roentgen therapy, one-fourth unit at weekly intervals for four doses, may be helpful. For the same also application of 25 per cent aluminum chloride in aqueous solution each night for ten days and then twice a week thereafter. For the anhidrosis of the body, the cautious use of pilocarpine is indicated. Keeping the patient in a cool environment is necessary to prevent discomfort and even danger. A course of ultraviolet exposures to the scalp is one indication for the alopecia. Another method is the use of direct stimulants such as the application at weekly intervals of Cutler's fluid (equal parts of chloral hydrate, phenol and tincture of iodine), but if skin irritation appears it must be promptly discontinued.

PYORRHEA ALVEOLARIS AND ARTHRITIS

To the Editor:—At the various symposiums on infectious arthritis which I have attended during the past several years, the consensus seemed to be that pyorrhea could not be regarded as a contributing focus of infection. I have been advised that some of the leading dental schools feel that this is a mistaken assumption. They believe that this infection is picked up by the lymphatics and is thus carried through the system and that, furthermore, the more modern treatments of pyorrhea block the lymphatic drainage from affected areas and thus prevent additional absorption. Please comment on these views.

Robert Hoffman, M.D., South Bend, Ind.

ANSWER.—It is assumed that by the term "infectious arthritis" the writer is referring to the so-called chronic non-specific infectious or rheumatoid (atrophic) arthritis. Despite the enormous amount of work done during the past seventy-five years to prove the microbic theory of rheumatoid arthritis, the cause of this disease is still unknown. It has not yet been definitely established that the disease is due to bacteria or even to bacterial toxins, nor has the role of infected foci been accurately determined. In the United States the majority of students of the rheumatic diseases are withdrawing from their former attitude of zealous adherence to the old idea that infected foci were a frequent cause of arthritis and that the removal of such infected foci could be expected to modify notably the course of the disease. The pendulum has swung away from the theory of focal infection simply because the results from the removal of various infected foci have been in the main so disappointing. Indeed, one of the prominent former advocates of removal of infected foci recently has stated that "The time has arrived for a complete reevaluation of the focal infection theory. Undoubtedly there are cases of infectious arthritis which result from focal infection. However, as far as typical rheumatoid arthritis is concerned, it would appear that chronic focal infection plays a comparatively unimportant role" (Cecil, R. L., and Angevine, D. M.: *Ann. Int. Med.* 12: 577 [Nov.] 1938). One view is that many infected foci may be the result, not the cause, of the disease; that is, that as the result of the general debilitating effect of rheumatoid arthritis the whole body is "run down," the general resistance of various tissues is lowered and, in some tissues which have become seats of lessened resistance, focal infections may develop secondarily (Pemberton, Ralph: *J. Bone & Joint Surg.* 53:879 [Oct.] 1935).

Infected teeth and pyorrhea are commonly found on examination of patients with rheumatoid arthritis, but they are also commonly found on examination of nonarthritic persons and of patients with forms of chronic arthritis (for example, osteoarthritis) not considered infective in nature. The majority of physicians and dentists have considered periapical infections more potent foci than gingivitis or pyorrhea. But representative of another view is the belief of J. V. Cogan that gingivitis is more important than periapical infection in cases of chronic arthritis and that such gingivitis requires special dental therapy

and not just cleaning (*J. Am. Dent. A.* 26:56 [Jan.] 1939). In contrast with this opinion is that of another student of rheumatic diseases who considered gingivitis "unimportant" and root abscesses "greatly overrated as a source of arthritis" (Monroe, R. T.: *Oxford Loose-Leaf Medicine*, Oxford University Press, 1939, chapter 15, pp. 367-404).

In support of the idea that gingivitis may play a role in the production of chronic arthritis can be mentioned the work of Cook and Stafne (*Dental Cosmos*, February 1939), who recovered organisms, chiefly *Streptococcus viridans*, from deep pyorrhea pockets of patients who had "chronic infectious arthritis" and, by injecting them intravenously into rabbits, were able to produce acute purulent arthritis in the rabbits, from the joints of which *Streptococcus viridans* was readily recovered. But in interpreting these results it must be noted that the articular lesions (acute purulent) in the animals did not resemble the chronic nonsuppurative lesions of the patients studied. Such experimental studies will be difficult to interpret until some characteristic bacteria or bacterial toxin can be consistently isolated from the joints or blood stream of patients who have rheumatoid arthritis or at least until the course of rheumatoid arthritis can be shown to be more significantly and more frequently modified by the removal of infected foci than has been shown to date.

The present attitude of most American rheumatologists is that arthritic patients with infected foci are certainly "less fortunate" than those without infected foci. Infected foci, including gingivitis, may well be harmful to the arthritic patient in a general way, if not in a specific way; hence their eradication is indicated, but no promises should be made that the articular disease will be notably altered thereby.

Much can be accomplished in the treatment of teeth affected with pyorrhea if the situation is recognized early before too much of the supporting tissues have become involved.

Treatment consists in thorough cleaning of the teeth, polishing of the exposed root surfaces, elimination of deep pockets and hypertrophied tissue and correction of traumatic factors. The patient should be instructed with regard to the necessity and importance of dental hygiene.

Generally speaking, if two thirds of the bony support of the single rooted anterior teeth is lost, or if the bifurcation or trifurcation of the multirooted teeth is exposed, the general practitioner should consider these teeth beyond treatment and they should be removed.

TREATMENT OF DEMENTIA PARALYTICA

To the Editor:—Should a middle aged patient with dementia paralytica whose serologic reaction has become negative after antisyphilitic treatment but whose clinical picture shows deterioration in spite of the negative serology be continued with treatment? Opinion seems to differ. According to the Vienna school one should keep on treating and one should go by the clinical picture rather than by the serologic findings. However, it seems that according to certain American schools of thought one would stop treating a patient such as the one mentioned.

M.D., Iowa.

ANSWER.—The answer to this question depends on whether the patient has already received fever therapy, preferably with malaria. If so, the situation is as summed up by Moore (*The Modern Treatment of Syphilis*, ed. 2, Springfield, Ill., Charles C. Thomas, 1941, p. 443): "Though improvement in the mental status may occur actually during the course of fever, it may also be delayed for several weeks or months. Worldwide experience has demonstrated, however, that if a change for the better does not appear within six months it probably will not occur at all. If malaria and the appropriate after-treatment have been unsuccessful in effecting any betterment during this period of time, the chance of obtaining it from any form of treatment, even including a second trial of fever therapy, is so small as to make further therapeutic efforts unjustifiable unless the family's finances are almost unlimited." This applies, however, only to malaria-treated paretics. If malaria has not already been employed for a patient such as the one described, it should be given a trial.

SULFHEMOGLOBINEMIA AND TUMOR GROWTH

To the Editor:—I have observed some cases in which sulfhemoglobinemia has seemed to retard the growth of malignant tumors and to make such tumors more sensitive to roentgen rays. I would like to have an informed opinion on this observation; furthermore, I would appreciate any reference to the literature.

M.D., Indiana.

ANSWER.—So far as is known there is no evidence that sulfhemoglobinemia retards the growth of tumors or renders them more sensitive to roentgen rays.

THE "ANOXEMIA TEST" AS AN INDEX OF THE CORONARY RESERVE

SERIAL OBSERVATIONS ON ONE HUNDRED AND
THIRTY-SEVEN PATIENTS WITH THEIR APPLI-
CATION TO THE DETECTION AND CLINICAL
COURSE OF CORONARY INSUFFICIENCY

ROBERT L. LEVY, M.D.
JAMES E. PATTERSON, M.D.
THOMAS W. CLARK, M.D.
AND
HOWARD G. BRUENN, M.D.
NEW YORK

The "anoxemia test," together with its clinical applications and limitations, has already been described in detail.¹ In principle it consists of permitting the patient to breathe a mixture of 10 per cent oxygen and 90 per cent nitrogen for twenty minutes or until cardiac pain appears. Measurements of electrocardiograms taken at intervals during this period reveal in patients with a diminished coronary reserve characteristic changes which are not observed in the presence of an adequate coronary blood flow. The occurrence of pain during the test has not been stressed as a diagnostic feature, because it represents a subjective reaction. In this respect, the present study appears to call for a modification in the point of view. The observations here reported were designed to furnish information concerning the value of a series of tests done over a period of time on the same patients, with particular reference to the diagnosis and the clinical course of coronary insufficiency.

MATERIAL AND METHOD

The group studied comprised 137 persons, on whom the test was performed 373 times. The duration of follow-up study ranged from six to thirty-nine months, with an average of twenty-one months. On 120 patients the test was done at least twice and on some as often as twenty times. The patients were classified according to the clinical diagnosis made before the initial test was carried out. In the control group were 25 "normal" persons, who did not have symptoms or signs of cardiac disease. Twenty-four patients were suspected of having coronary artery disease, chiefly because

of the complaint of cardiac pain, although no signs of heart disease were found. Sixty-seven patients had coronary sclerosis. This diagnosis was established by the presence of cardiac enlargement, an abnormal electrocardiogram or both. Many, but not all, of the 67 complained of anginal pain. In 45 no infarction was believed to have occurred; in 22 healed infarcts were known to be present. Ten had hypertension with no clinical evidence of coronary involvement. Among 11 patients with miscellaneous conditions 5 had rheumatic heart disease, 3 syphilitic aortitis and aortic insufficiency, 2 severe anemia and 1 acute pericarditis, probably of rheumatic origin (table 1).

Twenty-three patients died during the follow-up period, 15 of heart disease. In 11 of the 15 death was "acute"; that is, it occurred either suddenly or within a few weeks after an attack of coronary occlusion; in 4 it was due to congestive heart failure. Eight patients died of causes other than cardiac disease.

There were 96 men and 41 women; 123 were white and 14 Negro. In age the patients ranged from 20 to 79 years. The control group included persons from 31 to 77. There was no patient with coronary sclerosis under 40.

The data in each case were transferred to forms designed for the purpose, and a detailed statistical analysis was then carried out.² Only selected aspects of this study are here presented.

The test was performed as previously described, the criteria of a positive reaction being as follows:³

1. The arithmetical sum of the RS-T deviations in all four leads (1, 2, 3 and 4 F) totals 3 mm. or more.
2. There is partial or complete reversal of the direction of the T wave in lead 1, accompanied by an RS-T deviation of 1 mm. or more in this lead.
3. There is complete reversal of the direction of the T wave in lead 4 F, regardless of RS-T deviation.
4. There is partial reversal of the direction of the T wave in lead 4 F, accompanied by an RS-T deviation of 1 mm. or more in this lead.

The test should not be performed in the presence of congestive heart failure, within four months after known cardiac infarction or on the same patient more than once in twenty-four hours. If these precautions are observed, serious reactions may be avoided.

RESULTS OF FOLLOW-UP STUDY

"Normal" Patients.—There were 25 in this group, all without symptoms or signs of cardiac disease. None showed a positive result or died of cardiac disease. During the course of observation 2 died of cancer and 1 of pulmonary tuberculosis.

This investigation was aided by a grant from the Josiah Macy Jr. Foundation.

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Medical Clinic of the Presbyterian Hospital.

Read before the joint meeting of the Section on Practice of Medicine and the Section on Pharmacology and Therapeutics at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

Patients with Suspected Coronary Sclerosis.—There were 24 in this group. A positive reaction was observed in 3; in 2 of these the reaction subsequently became negative. None had pulmonary edema or congestive heart failure. In 1 death from acute cardiac disease occurred. In 21 patients the reaction was negative; in 1 of these it became positive. None in the course of the study had coronary occlusion, pulmonary edema or congestive heart failure.

Patients with Coronary Sclerosis.—There were 67 in this group. The reaction was positive in 30; in 11 of these it later became negative. In 6 of the 11 in whom a negative reaction was later observed pain occurred during induced anoxemia. Coronary occlusion, pulmonary edema and congestive failure each were observed once during the follow-up period. Four patients died of acute cardiac disease; 5 died of causes other than heart disease. In 37 the reaction was negative; in 14 of these, pain occurred during the test. Of the 37, 10 later showed a positive reaction, and of these 10, pain had appeared in 4 when the reaction was negative. Coronary occlusion and congestive failure each occurred once. Three patients died of acute cardiac disease; 2 died of causes other than cardiac disease.

TABLE 1—Material

Number of patients	137
Number of tests	272
Duration of follow up study, 6 to 39 months (average, 21)	
Clinical diagnoses	
Person normal	25
Suspected coronary sclerosis	24
Coronary sclerosis	67
No known infarction	45
Healed infarction	22
Hypertension	10
	11
Anemia	1
Pericarditis	1

Patients with Hypertension.—There were 10 in this group. The reaction was positive in only 1, in whom it remained so throughout the period of observation. This patient had no complications and survived. In 9 the reaction was negative. One of these later showed a positive reaction. One subsequently had congestive failure and survived. Four died of congestive failure.

Miscellaneous Patients.—There were 11 in this group. The reaction was positive in 2. One later showed a negative reaction, and pain occurred during the test. There were no later complications. Nine showed a negative reaction which in 1 later became positive. Two patients, both of whom had aortic insufficiency, died of acute cardiac disease; in both, although the reaction was negative, the test caused pain.

UNPLEASANT SYMPTOMS AND REACTIONS

On a number of occasions unpleasant symptoms occurred during the test but did not interfere with its completion. These were dizziness, headache, palpitation and irregular breathing. Unpleasant reactions which required termination of the test were observed eighteen times in 12 patients (table 2). Of these, vasovagal attacks were the most frequent and were observed eight times in 6 patients. In 3 patients on five occasions a state of panic developed. There was loss of consciousness twice in the same person, but curiously enough there was no change in either pulse rate or blood pressure. Consciousness returned in about one minute after 100 per cent oxygen was administered. Dyspnea was observed twice in 1 patient.

Though the dyspnea was not severe, it was deemed wise to terminate the observation. Pulmonary edema occurred once during a test done in November 1938, when the work was in its early stages. This is one of three similar reactions already reported.¹ Since we have observed the simple precautions already outlined, there has been no repetition of this disturbance.

TABLE 2—Unpleasant Reactions Which Required Termination of Test

Type of Reaction	Number of Times Observed	Number of Patients in Whom Reaction Occurred
Vasovagal attack	8	6
Panic	5	3
Loss of consciousness *	2	1
Dyspnea	2	1
Pulmonary edema †	1	1

* No change in pulse rate or blood pressure

† Occurred in November 1938, during the early stage of the work

It is our considered judgment that the test is safe for clinical use if properly performed. In the past four years it has been done in our laboratory 1,024 times on 442 persons. Unpleasant reactions have been observed forty-six times in 36 patients. There have been no serious effects; and repeated tests have not in any patient affected unfavorably the course of his disease.

SIGNIFICANCE OF A NEGATIVE REACTION WITH PAIN

In our previous studies importance was attached only to changes in the form of the electrocardiogram caused by induced anoxemia. This attitude was adopted because it was believed that pain, being a subjective reaction, might be an unreliable indicator. Patients vary in their susceptibility to painful stimuli, and in a few who are malingerers the result may be misleading. Certainly a method which is objective is preferable. In analyzing the present series, however, we were struck by the fact that in patients with coronary sclerosis who experienced pain during the test, even though no significant changes appeared in the electrocardiograms,

TABLE 3—Results of Test in Relation to Clinical Course in Sixty-Seven Patients with Coronary Sclerosis

Result of First Test	Number of Cases	Result of Follow Up Test Positive		Complications During Period of Observation *	Deaths	Complications + Deaths	
		Number	Percentage			Number	Percentage
Positive	30	19	63.3	3	4	7	23.3
Negative with pain	14	4	28.6	1	2	3	21.4
Positive + negative with pain	44	23	52.3	4	6	10	22.7
Negative, no pain	23	6	26.1	1†	1†	1	4.3

* The complications included are coronary occlusion, pulmonary edema and congestive failure

† Same patient

the cardiac lesions were often progressive. Some of these patients later showed a positive reaction, and a relatively large number during the follow-up period either had serious complications or died (table 3). In 63.3 per cent of a group of 30 patients showing a positive reaction on the first examination the result remained positive during the follow-up period; 23.3 per cent later either had coronary occlusion, pulmonary edema or congestive failure or died of cardiac disease.

Of a group of 14 patients showing a negative reaction with pain 28.6 per cent later had a positive reaction and 21.4 per cent had complications or died of heart disease. When these two groups are combined, making a total of 44 patients with either a positive reaction or a negative reaction with pain, 52.3 per cent showed a positive reaction during the follow-up period and 22.7 per cent had complications or died.

In contrast to the foregoing figures are the results obtained on 23 patients who had a negative reaction without pain. Of these 26.1 per cent showed a positive reaction on follow-up study but only 1, or 4.3 per cent, suffered from coronary occlusion and later died.

The importance of a negative reaction with pain is brought out in another way when the type of cardiac death is related to the result of the test (table 4). Of the entire series of 137 patients, 15 died of heart disease. Death was acute in 11; of these, 54 per cent showed a positive reaction and 36 per cent a negative reaction with pain. If these two groups are combined, it appears that in 10 of the 11 patients (90.1 per cent) in whom acute cardiac death occurred the reaction either was positive or was negative with pain. In contrast to these observations are the results in 4 patients

TABLE 4.—Type of Cardiac Death in Relation to Result of Test in Fifteen Cases

Death		Result of Test					
		Positive		Negative with Pain		Positive + Negative with Pain	
Type	Number	Number	Percentage	Number	Percentage	Number	Percentage
Acute cardiac.....	11	6	54	4	36	10	90.1
Congestive failure.....	4	0	0	0	0	0	0

who died of congestive failure. None of them showed a positive reaction or a negative reaction with pain. Thus a positive reaction or a negative one with pain indicates that there is a 90 per cent chance, in case of death, that the end will come suddenly or within a short time after an attack of cardiac infarction. If the reaction is negative, death, when it occurs, is apt to be associated with congestive heart failure.

The reasons for the occasional dissociation of pain and electrocardiographic changes during anoxemia are not clear. How painful impulses are initiated in the heart is imperfectly understood. When there is an oxygen want, many adaptive mechanisms are brought into play.⁴ Among these are variations in the cardiac output, the size of the heart, the heart rate, the arterial and venous pressures, the depth of pulmonary ventilation and the caliber of the coronary vessels. The manner in which these factors react on one another at different levels of anoxia and under varying clinical conditions undoubtedly plays a part in determining the effectiveness of the coronary blood flow. With the number of variables concerned it is not surprising that the result should be inconstant.

COMMENT

The use of the anoxemia test in differential diagnosis has already been indicated.¹ The following case is illustrative.⁵

CASE 1.—H. P., a man aged 61, a salesman, was admitted to the hospital on Dec. 29, 1939, with cough, dyspnea on exertion and "heaviness in the left side of the chest" of three weeks' duration. He had previously been in excellent health.

4. Wiggers, C. J.: Cardiac Adaptations in Acute Progressive Anoxia. *Ann. Int. Med.* 14: 1237 (Jan.) 1941.

5. This case was studied by permission of Dr. Robert F. Loeb.

He consulted his local physician, who found nothing abnormal on physical examination. A roentgenogram of the chest was said to show a metastatic growth in the mediastinum. He was referred to the hospital for complete study.

Examination revealed no cardiac enlargement. A souffle was heard above the left clavicle. The heart sounds were normal. The blood pressure in the right arm ranged from 150 to 170 systolic and from 85 to 100 diastolic; in the left arm it was 120 to 130 systolic and 90 diastolic. The first impression was that the patient had either carcinoma of the bronchus or an aneurysm of the aorta, probably the former.

The electrocardiogram showed low T waves and slight depression of the RS-T segments in the three standard leads. Roentgenograms of the chest showed a little dilatation of the ascending and the descending portions of the aorta. There were numerous dense streaky shadows radiating from the upper portion of the hilus of the right lung into the upper lobe on the right side. The appearance of these shadows suggested peribronchial fibrosis and scarring as the result of a tuber-

Fig. 1.—Result of the anoxemia test on H. P. (case 1). There had been cough, dyspnea and "heaviness in the chest" on effort for three weeks. Carcinoma of the lung or aortic aneurysm was at first suspected. The anoxemia test established the diagnosis of coronary sclerosis. a, control; b, after the patient had breathed 10 per cent oxygen for twenty minutes. There was no pain.

culous lesion. There were no changes suggesting a neoplasm. The heart was not enlarged.

The anoxemia test gave a positive result (fig. 1). There was a total RS-T deviation of 4 mm., and the T waves became inverted in leads 1 and 4 F. A diagnosis of coronary sclerosis was made.

In June 1940 the patient reported that he was having only occasional precordial oppression, relieved by the use of glyceryl trinitrate. An electrocardiogram was similar to the one previously made, and a roentgenogram of the chest likewise showed no change. The last follow-up examination was in November 1940. He was drinking rather heavily but did not complain of cardiac discomfort. An electrocardiogram taken at this time showed the T waves in leads 1 and 2 to be of even lower amplitude than before. In April 1941 word was received that he was in an institution because of chronic alcoholism.

Recently confirmation of the value of the test in diagnosis appeared in the paper of Evans and Bourne.⁶

6. Evans, Courtenay, and Bourne, Geoffrey: Electrocardiographic Changes After Anoxemia and Exercise in Angina of Effort, *Brit. Heart J.* 3: 69 (Jan.) 1941.

They administered a 10 per cent oxygen mixture for three to five minutes and found that of 20 patients with angina of effort in whom the four lead control electrocardiogram showed no significant change 6 gave abnormal ST and T wave responses. The period of anoxemia employed by these investigators was relatively short. It is not surprising, therefore, that in

Fig. 2.—Correlation of anoxemia tests of J. F. (case 2) with clinical course. He had attacks of cardiac pain for nine years, during which the diagnosis at various times was neuritis of the ulnar nerve, hyperthyroidism and cardiac neurosis. There was slight clinical improvement during the period of observation; the coronary reserve was variable but always reduced. In this and subsequent graphs the "zone of normal variation" covers the range of change caused by anoxemia in the electrocardiograms of normal persons. "Pain" refers to discomfort experienced during the test, and the time of its onset is charted. The "RS-T deviation" represents the sum of this measurement in all four leads. "T wave reversal" refers to this change in lead I, lead 4F or both.

their experience an exercise test produced an abnormal response a little more often than did the anoxemia test; but occasionally they noted changes in the electrocardiogram after anoxemia when no such changes followed exercise.

Through additional experience we have found no reason to change our criteria for a positive reaction. However, some significance, it appears, must now be attached also to a test which gives electrocardiographically negative results but during which pain appears. This is particularly true if the pain occurs during the first ten minutes of induced anoxemia. Four patients with negative reactions and such an early appearance of pain died within three years.

In reporting the results we have already directed attention to the relatively high incidence of complications and deaths among patients with coronary sclerosis who have shown a positive reaction or a negative reaction with pain, in contrast to the low incidence among patients with a negative reaction without pain. Similar evidence indicating the importance of a negative reaction with pain has been presented in the analysis of acute cardiac deaths as compared with deaths due to congestive failure. For the present, therefore, we are inclined to regard a negative reaction with pain as presumptive evidence of coronary insufficiency. The patients in whom this type of response is observed should be followed for further signs of coronary artery disease, and their management should be conservative.

The variable clinical course of persons suffering from coronary sclerosis is common knowledge. Anginal pain in particular tends to vary in severity and frequency. Changes in the form of the electrocardiogram may be observed at times without corresponding variation in symptoms. That either progressive damage or repair can take place in the heart insidiously, because of ana-

tomic changes, has been demonstrated clearly by Blumgart and his co-workers,⁸ who studied the coronary bed in diseased human hearts injected post mortem. They concluded that coronary occlusion if gradual and accompanied by the development of anastomotic circulation does not necessarily produce characteristic clinical manifestations. Variations in the coronary reserve can, however, be demonstrated in patients with this type of occlusion by changes in the response to induced anoxemia. The following cases serve to illustrate this point.

CASE 2.—J. F., a man aged 44, a taxi driver, in 1931 (nine years before his first visit to the hospital) began to notice pain in the left arm on walking. He was seen in the neurologic clinic and was given physical therapy for what was believed to be neuritis of the left ulnar nerve.

In 1935 he was first seen in the medical clinic because the pain in the left arm was worse and after exertion radiated to the left side of the chest. An electrocardiogram showed slight prolongation of auriculoventricular conduction. The PR interval measured 0.21 second. The Kline reaction of the blood was negative. The blood cell count was normal. Thyrotoxicosis was suspected, and partial thyroidectomy was recommended, although the basal metabolic rate was only +8 per cent. The operation, however, was not done.

By 1938 the pain had increased in severity and frequency. It occurred when the patient walked for three blocks. He described one episode of more severe discomfort which occurred while he was at rest. An electrocardiogram made on Nov. 30, 1938 showed inversion of the T wave in leads 2 and 3, together with a large Q_s. Posterior infarction was suspected, although the patient's physician regarded a cardiac neurosis as the most likely diagnosis and recommended reassurance. An anoxemia test done three weeks after the episode of more severe pain gave positive results (fig. 2). The patient experienced discomfort similar to his spontaneous attacks at the end of four minutes. The total RS-T deviation was 4.5 mm. There were no changes in the T wave. The diagnosis of coronary sclerosis was now established.

During the next twenty months he was seen at frequent intervals and numerous anoxemia tests were done. These all gave a positive result. He was last seen in April 1940. He was still having precordial pain radiating to the epigastrium.

He was able to drive his taxi and rarely required glyceryl trinitrate for relief.

That the healing of a cardiac infarct and the development of collateral circulation can be demonstrated by serial tests has been previously pointed out.¹ The following case indicates clearly that improvement in the state of the coronary circulation may take place during the second year following coronary occlusion.

Fig. 3.—Correlation for M. D. (case 3). Cardiac infarction occurred thirteen months before the first test. The clinical condition improved during the period of observation. The result of the anoxemia test, at first positive, became almost negative twenty-five months after the attack. Changes in the control electrocardiogram, however, increased.

CASE 3.—M. D., a man aged 60, a gardener, was admitted to the hospital on Feb. 7, 1939 with severe precordial pain of two days' duration. He had had occasional substernal pressure on exertion for six months. The more recent, severe pain persisted up to the time of his admission to the ward.

E.: The Modifying Action of Certain Drugs (Aminophyllin, Nitrites, Digitalis) on the Effects of Induced Anoxemia in Patients with Coronary Insufficiency. *Am. Heart J.* 19: 639 (June) 1940. Gold, Harry; Kvit, N. T., and Cattell, McK.: Studies on Purified Digitalis Glucosides: I. Potency and Dosage of "Digitaline Native" by Oral Administration in Man. *J. Pharmacol. & Exper. Therap.* 69: 177 (July) 1940.

8. Blumgart, H. L.; Schlesinger, M. J., and Davis, David: Studies on the Relation of the Clinical Manifestations of Angina Pectoris, Coronary Thrombosis and Myocardial Infarction to the Pathologic Findings. *Am. Heart J.* 19: 1 (Jan.) 1940.

Examination revealed a moderately enlarged heart, distant heart sounds and a systolic blow at the apex. The erythrocyte sedimentation rate was 40 mm. in one hour. The Kline reaction of the blood was negative. An electrocardiogram showed inversion of the T wave in leads 1 and 2 and depression of the RS-T segments in these leads. A roentgenogram of the heart showed left ventricular enlargement and prominence of the aortic knob. The diagnosis was coronary occlusion with

Fig. 4.—Correlation for H. L. (case 4). Cardiac infarction occurred twelve months prior to the first test. The clinical condition was unchanged during the period of observation; the coronary reserve diminished progressively. Death (suicide) occurred one month after the last test.

there was no pain but a total RS-T deviation of 6 mm. and inversion of the T wave in leads 1 and 4 F (fig. 3) were noted.

During the second year after the occurrence of infarction the precordial discomfort decreased. The patient had scarcely any pain except after severe effort, such as carrying a bucket up a flight of stairs. He rarely required glyceryl trinitrate for relief. He had been shoveling coal. The blood pressure was 155 systolic and 78 diastolic. An electrocardiogram now showed inversion of the T wave in lead 4 F. An anoxemia test done twenty-five months after infarction gave a positive result, but the electrocardiographic changes were minimal. There was no pain. The total RS-T deviation was 3.5 mm., and there was no reversal in the direction of the T wave. The size of the heart was unchanged.

The results of the test cannot be regarded as a quantitative expression of the degree of coronary insufficiency. On the other hand, in a given patient a trend, when present, paralleled the clinical course. In other words, if the reaction improved the patient reported that his discomfort, particularly pain, was less frequent and less intense; if the reaction showed greater deviations from normal the clinical condition was aggravated. This is illustrated in the following 2 cases, with their accompanying graphs.

CASE 4.—H. L., a man aged 40, an elevator starter, was admitted to the hospital Feb. 9, 1939 with precordial pain radiating to the left arm. He had had coronary occlusion in April 1938 (eleven months previously). He had been a heavy smoker. The heart was not enlarged. The first sound was diminished in intensity. The blood pressure was 128 systolic and 80 diastolic. The electrocardiogram showed inversion of the T wave in leads 2 and 3 and a large Q wave in lead 3. A teleroentgenogram of the heart showed no enlargement.

He was followed in the outpatient department during the next seven months. According to his reports there was little change in his symptoms. During this period three anoxemia tests were done, all of which gave positive results (figs. 4 and 5). The changes observed became progressively more marked. He committed suicide about one year after his first visit to the clinic. A postmortem examination was not done.

CASE 5.—C. A., a man aged 51, a railroad conductor, was first seen in November 1939, when he stated that he had had attacks of precordial pain for one year. Discomfort radiated

to both shoulders and arms. It was related to exertion and was relieved by the taking of glyceryl trinitrate. He was having three to five attacks a day. On examination there was no cardiac enlargement and the heart sounds were normal. The blood pressure was 150 systolic and 90 diastolic and during subsequent observations was never above 135 systolic and 80 diastolic.

During the following two years he was seen at infrequent intervals and the attacks of pain decreased in severity and frequency. In April 1941, he reported that they occurred only on the most severe exertion. The anoxemia test, which was repeated four times during a year, gave negative results at the end of nine months (fig. 6).

Four patients in the present series who died came to necropsy. The observations on 2 of these have already been reported.³

The third was a white man aged 63 who complained of epigastric pain. Roentgenologic examination of the stomach revealed a duodenal ulcer. He was included in the group of normal persons. An anoxemia test done twenty-four months before death gave negative results, and he did not experience pain while breathing the low oxygen mixture. He died in another hospital of carcinoma of the stomach. No pathologic change in the heart was noted at necropsy.

The fourth patient was a white man aged 39 who for five months had had epigastric and precordial pain induced by effort or excitement. Physical examination gave negative results. The blood pressure was 112 systolic and 78 diastolic. The electrocardiogram showed prolonged auriculoventricular con-

Fig. 5.—Result of the anoxemia test on H. L. (case 4). a, control; b, after the patient had breathed 10 per cent oxygen for twenty minutes. There was no pain.

duction, which at times reached 0.26 second. He was in the hospital for three weeks and was discharged with a diagnosis of chronic rheumatic heart disease. During the following year his symptoms increased and he was again admitted to the ward because of a severe attack of precordial pain which lasted one hour. The heart at this time was enlarged, the sounds were weak and a systolic murmur was heard at the apex. The blood pressure was 100 systolic and 68 diastolic. The tempera-

ture was normal and the leukocyte count was 8,600 per cubic millimeter, with 63 per cent polymorphonuclear cells. He died suddenly eight hours after admission. The final clinical diagnosis was coronary sclerosis and myocardial infarction.

Anoxemia tests were done nineteen, eighteen, fifteen and two months before death. During the first test the patient complained of precordial pain at the end of six minutes; but in none of the tests were significant electrocardiographic changes observed. At necropsy, there were advanced sclerosis of the coronary arteries, with occlusion of the right and circumflex branches of the left coronary artery, and old and recent infarcts of the myocardium, involving the left ventricle and the interventricular septum. There were no lesions of rheumatic fever. The changes in the heart were interpreted as indicating no significant diminution in the coronary reserve, in spite of the extensive disease.

It is not possible on the basis of the result of the test to predict the future occurrence of coronary occlusion. Several patients have suffered such attacks within a few months of the time that a negative reaction was noted. On the other hand, as has already been pointed out, patients with a positive reaction or with a negative reaction with pain are more likely to have this complication than those with a negative reaction. In short, the anoxemia test furnishes information concerning the

coronary reserve only at the time of its performance. It is an index within undefined limits of the functional efficiency of the coronary circulation and yields no information as to the nature or extent of pathologic lesions in the heart.

Fig. 6—Correlation for C. A. (case 5). There had been attacks of anginal pain for one month; clinical improvement was noted during the subsequent thirteen months. The result of the anoxemia test became negative, although control electrocardiograms showed increasing changes.

SUMMARY

1. This study is based on 373 anoxemia tests performed on 137 persons

during the past thirty-nine months. On all but 17 patients the test was done at least twice; on some it was done as often as twenty times.

2. A positive reaction was not observed in any patient without cardiac disease or severe anemia.

3. A positive reaction may be regarded as a sign of coronary insufficiency; a negative reaction does not exclude disease of the coronary arteries.

4. The occurrence of pain during a test with a negative result, particularly if it appears during the first ten minutes of induced anoxemia, affords presumptive evidence of a diminished coronary reserve. Under these circumstances the patient should be carefully observed for further signs of coronary disease and managed conservatively.

5. The test is simple and safe. In the past four years it has been done 1,024 times on 442 persons. Unpleasant reactions have been observed forty-six times in 36 patients. But there have been no serious effects, and the course of the disease has not been affected unfavorably as the result of repeated tests.

6. The test is helpful in the differential diagnosis of conditions producing pain in the chest. When the reaction is positive it serves to distinguish discomfort due to coronary insufficiency from that caused by other

disorders. It is useful in following variations in the coronary reserve and so in appraising the efficiency of the coronary circulation at the time of its performance. Serial observations reflect in a general way the trend of the clinical course. The test does not furnish evidence which makes it possible to predict the future occurrence of coronary occlusion. It affords an index within undefined limits of the adequacy of the coronary blood flow, but it yields no information as to the nature or extent of the pathologic lesions in the heart.

730 Park Avenue.

ABSTRACT OF DISCUSSION

DR. ROY W. SCORR, Cleveland: One of the most difficult diagnostic problems which the practitioner is occasionally called on to solve concerns the coronary arteries. In the absence of clear objective evidence of cardiovascular disease are the patient's symptoms those of coronary insufficiency? A person with coronary artery disease may be in imminent danger of death, and yet a most careful and complete examination may reveal no objective evidence of heart disease. Puzzling indeed is the individual primarily interested in establishing a claim for total disability on the basis of coronary insufficiency and angina pectoris. In the light of our present conceptions which regard Heberden's angina pectoris as a manifestation of myocardial ischemia, any safe procedure which loads the coronary circulation and which at the same time gives some objective index of the response would be a valuable test in the study of the occasional difficult case of coronary insufficiency. Such a test appears to be the "anoxemia test" as previously described by Dr. Levy and his associates, and further observations with it we have heard this morning. It seems fair to conclude that at least in Dr. Levy's hands the test has been safe and, when positive, has aided materially in differentiating coronary insufficiency from other disorders which cause chest pain. On the other hand, we must keep in mind that the induction of generalized anoxemia from the inhalation of low percentages of oxygen for fifteen or twenty minutes must be undertaken with great care; that the safety zone is narrow when one is dealing with atmospheres around 10 per cent oxygen, which correspond to an altitude of about 18,000 feet above sea level. Unless one is adequately equipped as is Dr. Levy and thoroughly aware of the dangers of generalized anoxemia particularly to the nervous system, one is not justified, I believe, in using the procedure. A disconcerting note regarding the practical use of the test in the diagnosis of coronary insufficiency was sounded by Dr. C. T. Burnett of Denver in a paper presented before the American Heart Association. He reported unpleasant and at times somewhat alarming reactions, as well as positive electrocardiographic findings in a number of persons with no signs or symptoms of coronary disease. He concluded that the anoxemia test was dangerous and of only limited value in the diagnosis of coronary artery disease. These conclusions from what appear to have been carefully controlled experiments should not go unchallenged.

DR. ARLIE R. BARNES, Rochester, Minn.: As I see the situation, the advisability of recommending this test in clinical practice hinges on three questions. First, is the test safe? Dr. Levy assures us that it is, and in his hands no serious results have followed its use; but he reports that unpleasant reactions were observed 46 times in 36 cases. These reactions frequently consisted of symptoms indicating irritation of the central nervous system. We know that nerve cells are the most sensitive of all tissues to anoxia. This suggests that the possible harmful effects of the test must be assessed as much on symptoms indicating effects on the central nervous system as on those referable to the heart itself. Second, may we accept without question the criteria of abnormal electrocardiographic changes defined by Dr. Levy under the conditions of his experiment? I am certain that Dr. Levy realized these may have to be modified and would welcome a test of their validity by other observers working under the same conditions. Unfortunately, the test cannot be appraised by reference to pathologic findings in the heart, for the test may give negative results, as Dr. Levy

has shown, when the heart is the site of maximal pathologic changes, and positive results when such changes are moderate or minimal. This is another way of saying that functional insufficiency of the coronary circulation can be estimated inadequately from pathologic changes observed in the heart at necropsy. Third, how frequently is the test indicated when a competent internist is unable to arrive at a diagnosis on ordinary clinical grounds? Dr. Levy's published account indicated that even in the presence of clinical evidence of coronary sclerosis the yield of positive electrocardiographic changes varies from 20 to 69 per cent. A negative test does not permit the exclusion of insufficiency of the coronary circulation, as has been pointed out by Dr. Levy and his associates. In the 40 per cent or more cases in which negative results from the anoxemia test are obtained, the clinician is still forced to rely on his clinical judgment in arriving at a diagnosis. For these cases a careful analytic history and tests of the patient's reaction to conditions increasing cardiac work will remain almost the sole basis for the diagnosis of inadequate coronary circulation. This is an important and refreshing approach to this subject. It is to be hoped that competent observers, adhering to the precautions stressed by Dr. Levy, will carry out similar investigations.

DR. C. T. BURNETT, Denver: I think Dr. Scott said he concluded, from my remarks the other day, that I felt the test was of no value. I wouldn't want to go that far. I would say that at present it is not of dependable clinical value. I am not yet convinced that the criteria may not be modified so that, even in this small 5 per cent which Dr. Scott and Dr. Barnes have spoken of, it may be of some value. I became interested in this work about two years ago. My associates and I began a study of 125 persons, in different age groups, as entirely normal as we could determine. If, in the course of the test, these persons had pain, any of these unpleasant manifestations which Dr. Levy mentioned, or anything else which raised any question as to their normality, they were cast out. In addition to these there were 62 cases, which made a total of 189 cases studied. The 62 represented those eliminated from the normal series. In this work we came reluctantly to two complete reversals of opinion, for at the outset we felt the test was dependable. We don't find any significant difference in the response of men from 50 to 60 years to that of men 20 to 30. We duplicated in every respect Dr. Levy's technic. Using this technic and the same apparatus, we found—in the majority of these normal subjects—a usual normal response, identical with that obtained by Dr. Levy and his associates. But in a significant percentage (19.2) of this group we encountered an abnormal response, according to Dr. Levy's criteria. The majority of these showed T_i inverted (Levy's third criterion). There wasn't any great difference in the age groups. We encountered vasovagal reactions, in all instances unpredictable. We encountered two convulsions. One occurred within thirty seconds after the man had responded to a question, when he had seemed to be perfectly conscious. I can't feel that a test which induces such a profound change as to lead that individual into a generalized convulsion is safe. We had no acute pulmonary edema but all the other unpleasant manifestations, I think, that Dr. Levy noted. The question has been raised as to the difference in response between Denver and New York. We used exactly the same percentage of oxygen as did Dr. Levy and—theoretically—we were subjecting our individuals to a little greater strain than in New York. Haden showed that at sea level the blood volume, hemoglobin, red cells and mean corpuscular volume are significantly lower than in Denver, as compared to studies by Mugaage and Andresen. So we feel that with persons who have lived in Denver there is sufficient compensation to make up for this difference.

DR. ROBERT L. LEVY, New York: In our experience, particularly in the hospital, the test has been of practical use in considerably more than 5 per cent of cases in which pain was referred to the chest. It has been helpful, for example, in differentiating discomfort due to gallbladder disease from that due to coronary sclerosis. Dr. Scott has referred to the use of the test as an aid in the determination of disability for insurance purposes. A negative test is without significance; a positive result indicates coronary insufficiency, though it does not measure the degree. In our hands the procedure has been safe,

provided the simple precautions outlined were observed. We are familiar with the effects of anoxemia on the nervous system mentioned by Dr. Barnes. But what happens to guinea pigs in an airplane at an altitude of 18,000 feet is hardly comparable to the effects in human beings, who at sea level breathe 10 per cent oxygen for twenty minutes and whose lungs are then promptly flushed out with 100 per cent oxygen. The fact remains that, in the course of three years, there has been no evidence of injury to the nervous system in our patients. The criteria of a positive test, of course, may have to be modified. We have already modified them once ourselves. The dissociation of pathologic and physiologic findings should be stressed. This test is not an indicator of anatomic changes in the heart. It is intended to afford a rough index of the efficiency of the coronary blood flow within limits which, as yet, are undefined. The studies of Dr. Burnett are not strictly comparable to ours. He has worked at an altitude of 5,000 feet and his subjects, therefore, have experienced atmospheric conditions at 23,000 rather than at 18,000 feet. This difference undoubtedly accounts for some of the discrepancies in the results. The inhabitants of Denver probably are not quite as well acclimatized as he has implied.

CARCINOMA OF THE JEJUNUM AND OF THE ILEUM

J. SHELTON HORSLEY, M.D.

RICHMOND, VA.

Carcinoma of the small bowel is often considered extremely rare. Though it is not common it is more frequent than is usually supposed. Sarcoma, however, is found more often in the lower part of the ileum than in the large bowel. Cancer of the ampulla of Vater and its adjoining tissue increases the incidence of carcinoma of the duodenum.

Three types of carcinoma of the jejunum and of the ileum may be considered: (1) the most common, adenocarcinoma; (2) carcinoid, or argentaffin tumor, and (3) melanocarcinoma.

The paper by Rankin and Mayo¹ in 1930, a later paper by Rankin and Newell² in 1933 and Raiford's³ articles on tumors of the small intestine in 1931 and 1932 were thorough and interesting. They included reports on tumors of the small bowel occurring almost to the time of publication of the reports. Few cases have been added to the literature within the period which these papers cover. At the Mayo Clinic between Jan. 1, 1919 and Oct. 1, 1929 Rankin and Mayo¹ found 31 cases of carcinoma of the small bowel as compared with 2,775 cases of cancer of the large bowel and the rectum and 2,646 cases of cancer of the stomach. Hoffman and Pack⁴ reported that of 228 cases of cancer of the small intestine the cancer was in the duodenum in 45.6 per cent.

In a study of the literature from the time of Raiford's article in 1932 to Jan. 1, 1941 I have found 384 cases of carcinoma and carcinoid of the jejunum and of the ileum. Of these cases, in 236 the tumor was adenocarcinoma of the jejunum or of the ileum, in 7 adenocarcinoma of Meckel's diverticulum, in 138 carcinoid

of the jejunum or of the ileum and in 3 carcinoid of Meckel's diverticulum. There have been 2 cases of what appears to be primary chorioepithelioma of the small intestine.

MELANOCARCINOMA

Primary melanocarcinoma in the jejunum or the ileum is rare, though a few cases have been reported.

Fig 1—External view of specimen from case 1. The proximal end is greatly dilated. The obstruction from the tumor is almost complete. There was severe kinking.

There have also been instances of what appears to be metastatic melanocarcinoma of the jejunum or the ileum from primary lesions of the skin. The surviving malignant cells seem to filter through the lungs and grow in the favorable tissue of the submucosa of the ileum.⁵

CARCINOID

Carcinoids, or argentaffin tumors, are interesting and unusual. They spring from argentaffin cells, which are distributed throughout the intestinal tract in man and many of the higher vertebrates. These tumors and cells are more common in the appendix, the cecum and the terminal part of the ileum. Most carcinoids are benign, but some are malignant and metastasize into the mesentery, the liver and even the brain.

A carcinoid of the intestine rarely surrounds the whole lumen and does not ulcerate. Consequently there is no blood in the feces and there are no toxic symptoms. Even the malignant type grows slowly, and resection of the bowel for an extensive carcinoid is justified even if there are metastases in the liver.

Carcinoid is apparently much more common than is usually believed. Keasbey⁵ has often observed it during necropsy in elderly patients, particularly men, who have died from other causes.

Grossly an argentaffin tumor on section presents a rather distinctive yellowish color. Histologically the cells of benign and of malignant carcinoids are practically identical.

ADENOCARCINOMA

Adenocarcinoma of the small bowel may be ulcerative, stenosing or polypoid (fungous). Usually the stenosing type is also ulcerative to some extent. Histologically the tumors are classed as simple adenocarcinoma, medullary carcinoma, scirrhus carcinoma and colloid carcinoma. Adenocarcinoma is by far the most common type. The medullary and scirrhus types are rare. Adenocarcinoma has a tendency toward retaining the original acinous formation. The cells arising from the mucous membrane infiltrate the wall of the bowel and break down into ulceration. Occasionally the differentiation of cells and the formation of acini is so nearly complete that the histologic diagnosis of carcinoma is made chiefly by the infiltration of the growth and by the number of mitotic figures and the appearance of the individual cells. They may, however, become more active and invade in sheets. Metastasis to the lymph nodes occurs early. Colloid carcinoma of the small intestine is similar to colloid carcinoma of the stomach or the colon.

The fungous, or polypoid, type may arise from an adenoma. It usually protrudes into the bowel and often produces obstruction either from direct mechanical

Fig 2—Section of the tumor in case 1, a colloid adenocarcinoma. There is a considerable amount of colloid material along with some adenomatous tissues. Slightly reduced from a photomicrograph with a magnification of 200 diameters.

occlusion or from intussusception. Intussusception occurs with the stenosing or napkin ring type, but it is infrequent compared with intussusception from polypoid or fungous carcinoma.

The early symptoms of carcinoma of the small intestine do not differ materially from the symptoms of

⁵ Horsley, J. S., and Keasbey, Louisa E.: Tumors of the Small Intestine, in Lewis, Dean Practice of Surgery, Hagerstown, Md., W. F. Prior Company, Inc., 1939, vol. 6, chap. 17.

incomplete obstruction. Martin⁶ has called attention to chronic incomplete obstruction of the small intestine. The symptoms often are vague and indefinite. The modern technic of roentgenologic study of the small bowel aids greatly in the diagnosis, but it must be followed through carefully over a period often of twelve or more hours. The main point is to deter-

Fig. 3.—Technic of end to end intestinal anastomosis. The rubber tube with additional perforations has been fastened to the posterior margin of the union with a single suture of silk. In order to facilitate its expulsion, long threads of silk or cotton may be fastened in the distal end. The presence of the tube provides against immediate obstruction from swelling and renders safer the insertion of additional suturing to turn in more of the bowel.

mine delayed emptying. Many conditions, such as avitaminosis, sprue, pellagra and hypoproteinemia, may cause this delay, but partial mechanical obstruction should always be considered.

The clinical symptoms in the earlier stages may be gaseous distention, heart burn, reflex pylorospasm and periods of diarrhea often alternating with periods of constipation. A lesion in the ileum when not completely obstructive frequently causes irritation, with consequent diarrhea. According to Martin,⁶ patients with partial obstruction may complain of a certain awareness of their intestinal motility and fatigue which occurs before meals and suggests the possibility of hypoglycemia. Such patients are frequently classed as neurotic. They often speak of discomfort rather than pain, and this discomfort may be accentuated by the ingestion of meals. Martin stated that sometimes it appears before the evening meal or may awaken the patient at night. Dizziness, he said, is another symptom experienced by many patients. The dizziness may be intense and may not be due to any apparent cause. Unexplained and unpredictable mild waves of nausea occur. The duration of symptoms varies from a few months to many years. Incomplete obstruction seems to occur with about equal frequency in the two sexes.

6 Martin, Ly: A Discussion of Some Conditions Producing Chronic Low-Grade Obstruction of the Small Intestine, *Mississippi Doctor* 18: 308 (Nov.) 1940.

When obstruction becomes complete it assumes the usual features of complete obstruction from any mechanical cause. It may occur from a particle of food lodging in the constricting napkin ring type of cancer. Occasionally the particle is dislodged, and the patient is temporarily relieved. The use of the Miller-Abbott tube combined with roentgen examination is often helpful in making a diagnosis.

Adenocarcinoma of the jejunum or of the ileum is more common in the upper part of the jejunum, near the ligament of Treitz. When the tumor is situated there, vomiting, particularly of large quantities of material, is a prominent symptom, even when the obstruction is not complete. If the tumor is in the lower part of the jejunum or in the ileum occasionally a movable mass may be felt, and when the mass slips from beneath the examining fingers readily it is suggestive of a tumor of the small intestine (Rankin). Occasionally there may be tarry stools, but occult blood is present in almost all cases of adenocarcinoma.

With ulcerating carcinoma of the jejunum or the ileum there is usually anemia, partly from the loss of blood and partly from the toxic products of the ulceration. With intussusception the pain is sharp and agonizing, and shock often develops soon. If the patient is thin there is visible peristalsis or counterperistalsis after any obstruction. If the tumor is high in the jejunum distention may be absent, but if it is low in the jejunum or in the ileum abdominal distention is severe.

The prognosis for malignant diseases of the small intestine is poor, probably largely on account of the difficulty of diagnosis and the lack of obvious symptoms until the condition is well advanced.

REPORT OF CASES

CASE 1.—H. K. W., a white man aged 59, admitted to the hospital April 11, 1939, had been in fairly good health until six months before admission, when he had mild indigestion,

Fig. 4.—Internal view of the tumor in case 2. The napkin ring portion is completely infiltrated with cancerous tissue except for a small area of mucosa. The proximal end is enormously dilated.

feeling as though his food would not leave his stomach properly. This gradually grew worse, and in the last three weeks nausea and vomiting had been severe. The indigestion usually appeared in the early afternoon about an hour after lunch but occasionally occurred even when the patient did not eat. Fullness and a desire to eructate were common. There had been no actual pain at any time. The patient felt better if he was quiet.

There was no blood or "coffee grounds" in the vomitus; it would often contain old undigested food. The stools were normal and were usually light in color.

There was borborygmus, with an indefinite sense of resistance in the upper part of the abdomen but no distention. The patient was sallow and the skin loose. Roentgenologic examination made a few days before admission to the hospital revealed obstruction in the upper part of the jejunum. There was no free hydrochloric acid in the gastric contents after twenty-five or after forty-five minutes; the combined acidity was 20 after twenty-five minutes and 16 after forty-five minutes. The gastric contents were bright yellow. The blood showed 4,687,000 red cells and 85 per cent hemoglobin, and the white cell count was 8,120, with 81 per cent polymorphonuclear cells. The Wassermann reaction was negative. The diagnosis was cancer of the upper portion of the jejunum.

Operation on April 12, with the patient under anesthesia with ethylene and local anesthesia, disclosed a firm growth in the

Fig. 5.—Section of adenocarcinoma of the jejunum (case 2). The acini are fairly well formed, and the tumor seems to be about grade 2½. Sections from tissue in the ovary and in the lymph nodes presented the same general structure (× 250).

upper portion of the jejunum just below the ligament of Treitz. There was no evidence of metastasis. Though the growth was adherent, it was fairly movable but could not be delivered into the wound. The tissues around it were vascular. After resection the upper stump was short. The lower stump was rotated slightly so that the left surface was posterior, and an end to end union was made. Before the suturing was completed a soft rubber tube 5 cm. in length was placed in the lumen and fastened to the posterior margin of the united bowel with a silk suture. A tube gastrostomy was made by inserting a catheter in the stomach near the greater curvature and bringing it out through a stab wound in the abdominal wall.

The specimen consisted of a segment of jejunum 15 cm. in length. The space distally from the tumor to the end of the specimen was 8.5 cm. The growth itself was 3.5 cm. in length. There was some infiltration into the mesentery. Obstruction was caused partly by angulation and kinking, though the center of the tumor showed on section almost complete occlusion of the lumen. The mucosa was edematous and pale yellow. There was no distinctly ulcerated area, though

the mucosa was eroded at one point opposite the mesentery. Microscopic examination revealed colloid carcinoma with intervals of adenocarcinomatous structure (figs. 1 and 2).

On December 22 the patient fell and fractured the right tibia and fibula just above the ankle. There was at that time no evidence of a recurrence or metastasis of the cancer. On March 5, 1941 he reported that his general condition "seemed to be excellent."

CASE 2.—Mrs. W. S. B., a white woman aged 57, had a cholecystectomy elsewhere on Aug. 4, 1940. Her symptoms were not relieved. There were intermittent episodes of vomiting which gradually became worse. She occasionally vomited food which had been taken into the stomach two days previously. Between the attacks food apparently passed through normally. Her mental condition was disturbed, and on the day of admission she had two convulsions in which the left side was chiefly affected. Roentgenologic examination made elsewhere before admission did not disclose any lesion in the gastrointestinal tract.

She entered the hospital on November 17 partly unconscious and vomiting at intervals large quantities of fluid in which there was bile. The abdomen was severely distended. Introduction of a Miller-Abbott tube relieved the distention but did not appear to alter the other symptoms.

A careful roentgen examination with the Miller-Abbott tube in position disclosed an obstruction apparently in the middle of the jejunum.

After a transfusion of blood and the intravenous administration of dextrose in Ringer's solution, she was operated on during spinal anesthesia on November 27. In the jejunum was an extensive constricting lesion that appeared malignant. It was removed along with a considerable amount of attached mesentery in order that the involved lymph nodes might be obtained. An end to end union was made, and a medium-sized soft rubber tube about 5 cm. long was sutured to the margin of the anastomosis before the final sutures were placed (fig. 3). There was also a superficial lesion in the cecum, apparently a contact metastasis. The terminal part of the ileum, the cecum and the ascending colon were resected, and an end to side union was made. A tumor of the right ovary and what seemed to be an inflamed appendix epiploica from the sigmoid flexure were also removed.

The specimens consisted of two segments of the intestine (one from the jejunum and another from the terminal part of the ileum, the cecum and the ascending colon) the right fallopian tube and ovary and an appendix epiploica from the sigmoid flexure. The segment of the jejunum was 98 cm. long. The distance from its upper end to the tumor was 43 cm. The proximal portion was greatly dilated. In the mesentery were some small lymph nodes. On section one could see that the tumor almost completely surrounded the lumen of the bowel, though there was one area of mucosa 0.5 cm. wide that was not involved. The growth had a napkin ring appearance and an irregular contour. There was a small ulcerated area; most of the tumor was firm (fig. 4). Microscopic sections showed adenocarcinoma with acini fairly well formed, about grade 2½ (fig. 5). In the segment of the ileum, cecum and ascending colon the lumen was not affected, but the superficial tissues over the ileocecal valve and over the ascending colon showed two lesions, one 1.75 cm. and the other 2 cm. in diameter. Microscopic sections from both showed the same type of adenocarcinoma as that in the jejunum. These lesions doubtless were contact implants. The growth from the ovary measured 4 by 2.5 by 2 cm. There was a constriction near its center. It was of the same structure as the jejunal growth, evidently an implantation metastasis.

The patient's general condition was fairly good after the operation, but her mental symptoms grew worse. It was thought that the mental condition might be caused by avitaminosis and malnutrition, though there was a possibility of metastasis to the brain. Evidences of increased brain pressure appeared, and after consultation with a neurologist it was thought that decompression was indicated. Two days after the abdominal

operation subtemporal decompression was done on the left side, with local anesthesia. After removal of the bone the dura did not pulsate. It was opened, and a small amount of clear fluid escaped. The cortex of the brain was edematous. While the wound was being closed the patient's respirations suddenly ceased and could not be restored.

Necropsy revealed that both anastomoses were in good condition. The upper one was 44 cm. below the ligament of Treitz. There was no evidence of metastasis except one lymph node at the base of the mesentery near the site of the resection of the jejunum and a superficial nodule in the sigmoid flexure. After the brain had been hardened it was examined by Dr. John S. Howe at the Medical College of Virginia, who reported as follows:

"The sections show multiple focal areas of hemorrhage and necrosis chiefly in the white matter of the cerebral cortex, with more or less well defined degenerative changes of the ganglion cells and rather diffuse endothelial proliferation of small vessels, blood in the subarachnoid spaces and one area of coagulation necrosis in the gray matter of the cerebral cortex. No evidence of any metastasis of the tumor is seen. Diagnosis: hemorrhagic encephalitis of undetermined cause. The lesions are somewhat suggestive of those seen in Wernicke's encephalopathy, which have been fairly well shown to be due to deficiency of vitamin B₁. However, the distribution of the lesions is different in this case and if they are due to some vitamin deficiency they are certainly atypical."

617 West Grace Street.

ABSTRACT OF DISCUSSION

DR. FRED W. RANKIN, Lexington, Ky.: Horsley has brought up to date a subject which is rare in occurrence but of more than academic interest. Tumors of the small bowel are rare whether they are benign or malignant. They are difficult of diagnosis and, more important, the malignant ones are uniformly of unfavorable prognosis. My experience with carcinoma of the small bowel was published in a paper in 1930 which reviewed 31 cases. Subsequently in 1933, with Newell, I reported 24 cases of benign tumors of the small bowel. The rarity of occurrence of either type of tumor is emphasized in all reports both in the foreign literature and in that of the United States and, it is interesting to note, the actual percentage varies in the writing of different authors. The symptomatology of carcinoma of the small bowel as a whole presents no characteristic pattern because of the usual failure of stenosis to develop early in the disease. The primary signs and symptomatology are directly related to intermittent obstruction and secondary anemia. The lack of obstruction and variability of the symptomatology depends on (1) the extent of the local growth, (2) extent and situation of metastasis, (3) individual resistance and (4) the grade of the carcinoma. Usually the symptoms are chiefly of intestinal origin. Their duration may vary from a few months to several years, the average being about one year and three months. In our series anemia was the usual picture, although varying with an average hemoglobin estimate of about 59 per cent. In 9 of the cases the reading was below 40 per cent, and the anemia was so progressive as to mimic a picture of pernicious anemia. The determination of the type of anemia whether primary or secondary is relatively easy for a hematologist, but it should be emphasized that this pronounced anemia without visible loss of blood is also a symptom of carcinoma of the right colon and here, as in colonic cancer, repeated tests for occult blood are usually of significance in suggestive cases. Roentgenologic examination is important from a negative standpoint, and only an occasional case will be actually diagnosed by the roentgen ray. Pathologically these tumors are usually adenocarcinoma developing on degenerating polyps, or of the ring type, similar to that found in the lower left colon. Metastasis occurs relatively early, owing to the rich lymphatic supply of the small bowel, and because of the impairment to the digestive function of this portion of the alimentary canal resection of the tumor when

possible is desirable. The deplorable prognosis is one of the most unfortunate features of this disease. The range of life following successful surgical removal in our series was from one month to three years, and the average was less than one year. In our experience aseptic end to end anastomosis was the procedure of choice and lateral anastomosis sidetracking the growth was useful as a sidetracking palliative maneuver.

BLOOD PROCUREMENT FOR THE ARMY AND NAVY

PRELIMINARY REPORT

EARL S. TAYLOR, M.D.

Technical Consultant, Volunteer Blood Donor Service,
American Red Cross.

NEW YORK

In January 1941 the Blood Transfusion Association¹ concluded its project in supplying blood plasma to England. This work, carried on in cooperation with the New York chapter of the American Red Cross and subsequently with the assistance of the Brooklyn chapter, was performed almost exclusively by volunteers in nine hospitals in New York and dealt with 17,000 donors during the period August 1940 to January 1941. This was the first time in the history of the country that the procurement of blood was carried on in such a large scale. It was apparent that not only had considerable material aid been given to Great Britain but the knowledge gained in the operation of this project would be invaluable in case of a national emergency in this country.

In February 1941, to fulfil the request of the surgeon generals of the Army and Navy of the United States for 15,000 units of dried plasma, a pilot bleeding unit was established in New York at the Presbyterian Hospital under the auspices of the New York chapter of the American Red Cross. This unit was under the direction of Dr. Charles R. Drew, who had been the medical supervisor of the Blood for Britain Project. It was felt that, by the establishment of such a unit before the need for larger quantities of blood became pressing, the technic and organization could be standardized on the basis of actual experience. This unit was organized with the following aims in view:

1. Efficient collection of large quantities of blood in as short a time as possible.
2. The development of a technic which would enable this to be carried out in as simple a manner as possible without any danger to the donor or damage to the blood obtained.
3. Flexibility of organization and technic so that whether whole blood, serum or plasma was requested the demand could be met with a minimum of adjustment.
4. Adaptability of the organization for civilian use at the conclusion of the present emergency.

This unit was in full operation in May 1941 under my direction when the request for an additional 200,000 units was made. At that time, the medical departments of the Army and Navy requested the American Red Cross and the Division of Medical Sciences of the National Research Council to organize a cooperative project for the collection of blood from volunteer donors. These donors were to be solicited by the American Red

The blood that has been taken in this project has been processed by Sharp & Dohme Laboratories, Glenolden, Pa., whose cooperation in all phases of the work has been of great value.

1. Report of the Blood Transfusion Association Concerning the Project for Supplying Blood Plasma to England, carried on jointly with the American Red Cross from August 1940 to January 1941. Stetten, DeWitt: Blood Plasma for Great Britain Project, *Bull. New York Acad. Med.* 17: 27, 1941.

Cross through their various chapters in the localities in which it seemed advantageous to establish bleeding units. The technical aspects of the project, such as determination of the type of equipment, technic and personnel were to be supervised, in an advisory way, by the National Research Council.² During the period Feb. 3 to Sept. 18, 1941 this pilot unit has had experience with 10,000 volunteers. This report is concerned with the data that have been accumulated in the conduct of the project.

GENERAL CONSIDERATIONS IN RELATION TO THE DONOR

Every consideration should be given to the volunteer donor. The donor requirements and the technic of bleeding have been set up to afford him a maximum of protection. It is important that all his activities at the bleeding station be under the direct supervision of the physician in charge. All questions as to eligibility of donors and any untoward reactions that occur while the donor is at the station should be brought immediately to the physician's attention. This not only facilitates the operation of the unit but adequately covers the medicolegal aspects.³

It is well established that the withdrawal of 500 cc. of blood has no deleterious effect on the health of properly selected donors. In fact it seems to promote the sense of well-being in some donors and improve their general health.⁴ Serious accidents⁵ have rarely been reported but none have occurred with this unit.

The chief problem confronting the bleeding unit is that of syncope. Not only is it deleterious to the morale of the other donors but it greatly hampers the efficiency of the bleeding unit. A pleasant, interested attitude on the part of the entire staff is of paramount importance. The operation of the bleeding unit should give the appearance of easy and unhurried efficiency. This adds greatly to the impression that the donation of a pint of blood is a simple procedure and not a major ordeal.

Although the donors should be instructed not to eat a fatty meal for at least four hours before coming to donate their blood, it should be emphasized that they should not fast. Some simple nourishment should be taken before coming to the bleeding station. At the conclusion of the venesection facilities should be available for the donor to rest for a short period and to receive some form of nourishment.

Just what part the type of bleeding room plays in the problem of fainting is difficult to evaluate. In general there are two types of arrangement that allow for efficient operation. One has individual cubicles with either fixed or movable partitions, and the other is a common bleeding room with all the bleeding couches in full view. This unit has had experience with both arrangements and has found little to choose between the two plans.

2 The National Research Council assumed responsibility under the terms of the agreement.

PROCUREMENT OF THE DONOR

Duran-Jorda,⁶ in reporting his excellent work in the Spanish Civil War, stated that "the success of any transfusion service depended on the organization of the donors." No amount of technical perfection and equipment will be of any value if the supply of donors is not adequate, hence the organization of an efficient recruiting service should be the first step in setting up a bleeding unit. Unless a center can provide at least 50 donors a day, it is not practical to set up a bleeding unit in that locality. Before the unit begins operation, at least 300 donors should be signed up to give blood. The recruitment of donors, particularly in large communities, cannot be done simply by advertising with a few posters and newspaper articles. Experience has shown that personal contacts with fraternal groups, churches, unions, office and department store employees and factory groups is the only way that a large number of people can be reached. This entails much detail work and careful preparation. A single day's bleeding should be planned at from ten to twelve days in advance.

It was quickly ascertained by the pilot unit that if a large number of donors were to be obtained the bleeding unit would have to go to the donor. This not only minimizes the amount of time lost from work by factory or store employees but obviates the necessity of people in the outlying districts coming relatively long distances to a central depot.

The actual organization of the recruiting services will depend largely on the facilities of the local Red Cross chapter. The New York chapter of the American Red Cross, at the instigation of the executive director, General Robert C. Davis, has established a volunteer blood donor service under the direction of Colonel Earle Boothe. This service sends cards to each of the donors showing the amount of blood given, the type⁷ and a report of the serologic test. It is much like the certified donor cards that the various volunteer and professional transfusion bureaus throughout the world have employed.⁸ Not only is this information of value to the donor himself but it also serves in communities and store and factory groups as a foundation on which a local volunteer transfusion service may be established. Such a service is of great value to a community in dealing with its local health problem.

DONOR REQUIREMENTS

The following requirements have been established, after a survey of the standards of the various volunteer services that have been in operation in this country⁹ and in Europe¹⁰ and, in particular, those which have

been set up by the British,¹¹ French,¹² Spanish,⁶ Australian¹³ and Canadian¹⁴ transfusion services during the present war. Certain of our own modifications have been added as the project has progressed:

1. Age: Donors between 21 and 60 years of age are accepted. Under no circumstances is the age limit of 60 to be exceeded. Written permission is required from the parents or legal guardian before suitable minors of either sex may give blood.
2. Sex: Both male and female donors are accepted.
3. Race: Only white donors are taken.
4. Temperature: A donor is not acceptable if the temperature by mouth (three minutes) exceeds 99.5 F.
5. Hemoglobin: No donor is acceptable unless the hemoglobin level is 80 per cent or above. The hemoglobin is to be determined by one of the generally accepted technics (e. g. Dale, Tallqvist, Sahli).
6. Blood Pressure: No donor is acceptable unless the systolic blood pressure is between 100 and 200 mm. of mercury.
7. Pulse: The pulse is to be recorded. Particular note is made of irregularity as well as decided bradycardia or tachycardia.
8. History: The donor is asked the following questions:

1. When did you last donate blood? (At least eight weeks must elapse between each donation.)
2. Have you had any illness in the last month?
3. Have you ever had malaria? tuberculosis?
4. Did you ever have shortness of breath?
5. Have you had swelling of the feet?
6. Have you had a persistent cough?
7. Have you pain in the chest?
8. Have you coughed up blood recently?
9. Do you have fainting spells?
10. Do you ever have convulsions?

If these requirements are adhered to, protection is given to the donor and the possibility of transmission of disease from donor to the eventual recipient is reduced to the minimum. Syphilis, malaria, influenza, measles, allergy, smallpox and disease caused by the rickettsia organisms, and, in the Orient, parasitic diseases such as filaria, have been reported¹⁵ as transmitted by transfusion of whole blood. The entire question of syphilis will be dealt with under the heading "serology." All persons with recent attacks of malaria or who have had several infections in the past should be turned down. This protects also the donor, since the withdrawal of 500 cc. of blood has been known to cause an exacerbation of the disease. The pooling of the plasma of from 25 to 50 persons should eliminate the danger of transference of any allergy. The history and the evaluation of the general health of the donor should reduce to a minimum the possibility of transference of the other conditions mentioned. Further regulations may be drawn up to control the transmission of any disease that is known to be endemic in a particular locale.

THE BLEEDING SET

It was recognized at the outset of this project that the number of satisfactory ways of obtaining blood were myriad. However, when this subject was considered it was felt that whatever bleeding set was used should meet certain general requirements.

1. It must be a completely "closed" system.¹⁶ This means that there should be no manipulations in the assembly of the set from the time it is originally autoclaved until the venesection is completed.

2. There should be no chance for transference of any air into¹⁷ the bleeding bottle which does not pass through a cotton bacterial filter.

3. The parts of the set should be as few as possible. They should be easy to clean and, in order to minimize air leaks, there should be as few joints as possible between the parts.

4. The diameter of the tubing¹⁸ that carries the blood from the vein into the bottle should be appreciably larger than that of the needle in order that the flow of blood will be rapid and uninterrupted.

Fig. 1.—The bleeding set used by this unit. The bottle contains 50 cc. of 4 per cent sodium citrate solution. The set is sterilized in the muslin bag.

5. The bottle should have an adequate diameter, approximately 3½ inches, so that there will be no need to agitate the blood to prevent clotting during its collection.

6. The bottle should have a capacity of 550 cc. so that there will be a minimum of air space remaining after the withdrawal of the full 500 cc. of blood.

7. Mouth suction¹ or negative pressure¹⁹ obtained by anything other than a simple hand pump should never be employed.

8. The inlet tubing of the set should be transparent and preferably of latex. Gum rubber tubing tends to stick together after being autoclaved.

9. The needle should be of a fairly large caliber. Gage 15 has been found to be suitable for both male and female donors.

The exact dimensions and shape of the bottle are of little moment but the bottle should be designed to fit the available centrifuges and be readily obtainable and easy to clean. In order that the inlet tubing fit tightly about the needle, it is preferable that it have a hose hub. The needle that has been employed in this project has a cross bar just distal to the hub, similar to the Lewisohn needle. This type is strongly recommended, as it facilitates handling without contamination and can be left in place in the donor's vein without being held or having some sort of adhesive strapping applied.

Figure 1 shows the bleeding set used by this unit. The bottle contains 50 cc. of 4 per cent sodium citrate.

ORGANIZATION

There are two main functions of a blood donor service—that of recruiting the donors and that of bleeding them. It suffices to say that the recruiting of the donors should be carried out by a full time director. The organization of his staff depends on the individual requirements of the local Red Cross chapter.

The most effective personnel for a bleeding unit is one physician, one secretary, four nurses and one or two

pulse and history are taken by one of the nurses at a second table. The donor is then referred to a dressing room. White gowns similar to the so-called Hoover apron have been provided for the donor by this unit. He is then directed to the bleeding room, where his blood pressure is determined. The physician in charge checks the record card to see that the donor has met the minimum requirements.

The basis of the arrangement of the bleeding room is a unit of two beds and a work table under the supervision of one nurse (fig. 2). As many as six of these units can be efficiently handled by one experienced physician. Whether a single large bleeding room or the cubicle system is adopted the floor plan should be such that the physician can at all times oversee the bleeding of each donor.

VENESECTION

If the donor fulfils the established requirements, a small area about the site of the vein selected for venesection is prepared with soap, alcohol, iodine and alcohol. An intradermal wheal of 1 per cent procaine hydrochloride is administered. The bleeding set is removed from the muslin bag by the nurse. The physician unsheathes the needle from its Wasermann tube covering and introduces it into the vein. Unless something untoward arises, the rest of the phlebotomy is carried out by the nurse. It should be noted that no sterile drapes, masks, gloves or special gowns are used. "Cutting down" on a vein is never employed.²¹ No more than two attempts to obtain blood should be made on a donor.

The procaine hydrochloride is supplied in 2 cc. syringes, a separate needle being used for each donor. These needles are kept in individual cotton-stoppered tubes. The syringes are all filled at the start of the bleeding day by a nurse using operating room technic. Each syringe will supply sufficient procaine hydrochloride for six or eight

wheals and is not refilled unless it has been autoclaved.

The donor assists in maintaining the flow of blood by slowly opening and closing his hand. Suction is rarely employed and then only a small hand pump is used.

At the conclusion of the bleeding, the inlet tube is clamped as close to the bottle as possible and the serologic sample obtained by stripping the distal portion of the tubing. The arm is cleansed and a suitable dressing applied over the site of venepuncture. The bleeding bottle is then properly tagged and the sticker applied to the serologic sample. Both are placed immediately in a constant temperature ice box. After the donor has rested on the bleeding couch for ten minutes he is directed to the refreshment room.

REFRIGERATION AND TRANSPORTATION

The cooling of the blood²² should be begun as soon as possible after it has been taken. When the unit is operating at a fixed station the blood taken should be placed in a constant temperature ice box which maintains a range of from 2 to 4 C. This ice box should

Fig. 2.—This unit of one work table and two beds, under the supervision of one nurse, is the basis on which the bleeding center is set up. It will be noted that men and women use the same bleeding room.

shipping clerks. This staff is similar to that employed by the various depots of the British Transfusion Service.²⁰ Such a unit can easily care for 75 to 80 donors in from four to six hours and has bled 100 male donors in less than four hours. With a personnel of this size, two functions of the work are left to volunteers, namely receptionist work and the dispensing of refreshments. The unit is organized on the basis of employing as few physicians as possible, with emphasis on a highly efficient nursing group. Not only is this a workable plan but in times of national emergency it would permit widespread extension of the work with the addition of a relatively small number of physicians.

If feasible, the space employed should be so arranged that the donor progresses consecutively from registration through to the completion of the bleeding. On arrival at the bleeding station, the donor is directed to the unit's secretary, who registers him on the permanent record card and witnesses the signature of the release. At this time, the tag for the bleeding bottle and the sticker for the serologic sample are filled out. The hemoglobin content is determined and the temperature,

be employed as a blood refrigerant. However, since the box is in use for a relatively short period of time, is frequently opened and the solidified carbon dioxide has no direct contact with the blood, it has been found that it is safe to use such a container for the mobile unit.

If the blood is not allowed to go below zero or above 10 C. during the time that it is in transit to the processing plant, no damage will be done to the blood. A large, portable refrigerator box, known as a Church container, has been successfully employed by the New York unit. This container, which has racks for 80 bleedings, must be precooled with solidified carbon dioxide for from eight to twelve hours before use. A bunker is provided for the ice that is used as the refrigerant in transit.

SEROLOGY

It can be seen from table 1 that there were 24 persons who gave a positive serologic reaction out of 9,693 accepted—a rate of 0.249 per cent. Blood from these persons of course was discarded. This incidence is quite low but not unusually so when compared with figures gathered from similar volunteer services.²⁴ Each of these 24 persons was interviewed and none had any previous knowledge of having had syphilis. Inquiry regarding the history of syphilis is distasteful to some persons and with this group questioning regarding it would not have elicited any pertinent information.

Total.....	307

There are at least 20 well authenticated cases in the literature of transmission of syphilis²⁵ by transfusion of whole blood when the donor's serologic reaction was negative. Recent work²⁶ has shown that it is doubtful

whether *Treponema pallidum* will survive three days' refrigeration at 5 C. The plasma collected in this project is refrigerated for at least two weeks at a temperature far below this. More recent work has shown further that when serum or plasma is desiccated²⁷ the organisms do not remain viable even when heavily infected specimens are tested. I believe that these data definitely rule out any possibility of the transmission of syphilis by the plasma that has been collected.

All dealings with the donor regarding a positive serologic reaction should be undertaken with the full recognition of the medicolegal complications involved. The word "syphilis" should not be mentioned in any written communications between the bleeding center and the processing plant or between the physician and the donor. Reports from the processing plant should simply state "Sample # — was found to be unsatisfactory." Every effort should be made to secure a second sample from the donor for a confirmatory test at another laboratory. The donor is then requested to give his written permission for the results to be forwarded to his personal physician. By dealing with the matter in this fashion, the physician in charge properly disposes of his public health obligations and terminates the physician-patient relationship that had been

Fig. 3.—A standard 1 ton delivery truck is used as the ambulance for the mobile unit. This can carry equipment to take care of 200 donors.

established by the donor coming under his care at the bleeding center. Such a program has been successful without exception in this unit and has had no unpleasant sequelae.

CONTAMINATION

When material as highly susceptible as liquid plasma is being dealt with the problem of contamination is very real. The chief factors in the maintenance of sterility by the bleeding unit are:

1. The bleeding set should be autoclaved in a protective muslin covering so that the entire set may be kept sterile up to the time of its use.
2. No bleeding set should be used more than fourteen days after being autoclaved.
3. The containers used to ship the bleeding sets should be locked with wire seals.
4. If there is any question of a mechanical defect in any portion of the bleeding set, the set should be discarded.
5. A set should be discarded if any foreign body appears in the citrate solution or in the inlet tubing.
6. If either of the cotton filters are wet, the set should be discarded.
7. All palpation for difficult veins should be done before the arm is prepared, so that venepuncture may later be performed by a "nontouch" technic.

8. A needle should not be used for more than a single penetration of the skin.

9. If an air leak or other mechanical defect appears during the course of bleeding, such a set should be referred for an individual sterility test.

10. The contamination rate rises in proportion to the number of persons performing the venesection.

11. The sterile material employed must be prepared by autoclaving at 250 C. for thirty minutes.

12. Absolute refrigeration control must be maintained from the time that the blood is taken until it reaches the processing plant.

13. Transportation should be so arranged that the plasma can be separated from the cells within forty-eight hours after the blood has been withdrawn from the donor.

14. The personnel should be on a full time basis. Volunteers should have no part in the actual bleeding of the donor.

By employing the "closed" system, many of the factors in contamination that are inherent in other types of bleeding sets are obviated. As simple as is the bleeding process with this technic and equipment, it is paramount that each small detail is meticulously adhered to. It is the accumulation of what may seem to be small and unimportant variations that produces contaminations.

No bactericidal or bacteriostatic agents, such as the drugs of the sulfonamide group,²⁸ have been used as a preservative for the blood as it is taken. Experimental work²⁹ carried out in connection with this project has cast considerable doubt on the efficacy of these drugs in eliminating contamination.

MOBILE UNIT

More than 40 per cent of the blood obtained by the New York bleeding center has been collected by a mobile unit. The personnel and the arrangements of the space available should be as similar as possible to those

outlined for the fixed group. This mobile unit has operated within a radius of 100 miles from New York. Bleeding has been done in factories, recreation rooms of office buildings and department stores, college infirmaries, community centers, woman's clubs, church parlors, hospital wards and in the open at the American Red Cross camps. The blood taken has been transported

0.743 breakage
1.200 contamination
6.002 %

over all types of terrain and during all seasons of the year. So far, there has been no more loss due to breakage, hemolysis or contamination than has occurred with the fixed group. The feasibility and necessity of establishing mobile units in war time is borne out by the experience of the British Transfusion Service.³⁰ Implications for its use in times of peace for civilians should be borne in mind. This has been previously suggested by DeGowin³¹ and by Strumia and McGraw³² for areas in which the population is highly decentralized.

No special material is necessary to equip the mobile unit other than the portable refrigerators. A standard 1 ton delivery truck (fig. 3) will carry material and refrigerating facilities for 200 donors. The equipment is identical with that of the fixed group, except that beds, chairs and tables are of the folding or collapsible type. Duplication of equipment and personnel gives complete flexibility to these two units and allows for some shifting of personnel, when a particularly heavy load is imposed on either one.

RESULTS

Table 1 gives a statistical summary of the experience with 10,000 persons who presented themselves as donors during the 178 bleeding days between Feb. 3 and Sept. 17, 1941. This is an average of 59 donors a day. At no time has the capacity of the unit been approached. The two units that have been in operation can easily handle 3,500 donors a month, working a five and one-half day week.

It will be noted that 307 prospective donors were rejected. The reasons for these refusals are noted in table 2.

It is interesting to compare the results obtained from the two sexes (table 3): 53 per cent of the donors were males and 47 per cent were females. Undoubtedly there are more females who present difficulties in venesection, but when the figures are broken down according to sex the technical difficulties encountered with the females are not nearly as impressive as might be expected.

In a project of this size it is necessary to determine how many full bleedings arrive in a usable condition at the processing plant as compared to the number of persons who come to give blood at the bleeding center. Such a figure includes losses from all sources. The bloods of 24 donors (0.249 per cent) were discarded because of a positive serologic reaction. Breakage in

handling at the bleeding unit, in transportation or in centrifuging accounted for the loss of seventy-two bottles (0.743 per cent). Fifty of these were lost in a single shipment which was improperly packed. With the type of equipment in use and the facilities for transportation now employed, the loss from breakage in the future should be negligible. Twenty-seven liters of plasma citrate mixture (1.2 per cent) was lost by contamination. This represents the blood from ninety-nine bleedings in two pools. The loss from all causes amounts to 6.002 per cent,³³ in other words, to have 100 usable bleedings at the processing plant approximately 106 donors must come to donate their blood (table 4). Although every effort is made to obtain a full bleeding from a donor, this is not always possible. It is necessary therefore to determine the average plasma-citrate yield from each bleeding. This was 273 cc. However, since 300 cc. of plasma is required to fill the final dispensing unit, it is necessary to have 109 usable bleedings to produce 100 units of dried plasma. If the 6 per cent loss previously mentioned is added, 115 donors are necessary to yield enough material for each 100 units of dried plasma-citrate mixture.

Presbyterian Hospital.

THE PRINCIPLE OF TRACTION IN THE TREATMENT OF URETEROLITHIASIS

ROY P. FINNEY, M.D.
SPARTANBURG, S. C.

Tiny calculi impacted in the pelvic segment of the ureter can be as tantalizing to the physician as they are agonizing to the patient. As a rule these curious pseudogeologic formations should be removed as quickly as possible, before the onset of certain painful and dangerous complications and/or sequelae.

The trouble one may encounter in extracting a stone from the ureter varies greatly and is wholly unpredictable. Thus a relatively small stone may require open operation, while another much larger may respond favorably to the slightest manipulation. This unpredictable behavior doubtless is the fault of the ureter, which from the standpoint of biomechanical efficiency leaves much to be desired. It is too small in caliber, too fragile and too keenly sensitive to reflex stimuli. A combination of these and other faults makes the removal of a stone by manipulation one of the most uncertain and often one of the most difficult procedures in medicine.

Dr. Hugh Hampton Young, first in so many beneficial contributions to the science of urology, was first to discover that a ureteral calculus may be made to pass by poking and prodding with instruments of various sorts inserted into the ureter by way of the newly invented cystoscope. His first success with this method came in 1902.

The passage of forty years has brought certain technical refinements and a dignified name to Dr. Young's original procedure. The physician may now select from a large number of ingenious instruments and an array of vastly improved cystoscopes. The method itself, in

which an operator has at the stone with unlimited stretchings, pokes and prods, is called "manipulation."

Manipulation is no doubt a valuable addition to genitourinary procedure. However, urologists differ considerably in their estimate of its worth. C. B. Squires, reporting on the treatment of 606 patients at the Crowell Clinic (1915 to 1930) said: "Manipulation was successful on 528 patients. Only 44 required open operation."

Likewise, Fowler and Champion have been highly successful with manipulation. In their office practice 76 per cent of patients responded to conservative treatment, an excellent record considering the fact that the patients usually continued work throughout treatment. Their favorite instruments were catheters and the spiral dislodger.

In contrast there is Higgins' review of 350 cases of ureteral calculi in which treatment was given at the Cleveland Clinic. Manipulation failed or was not attempted in 228 cases. However, the figures are misleading to any one unacquainted with Higgins' exceptional success in open operation. In 228 cases of ureterolithotomy he and his colleagues had a mortality of less than 1 per cent. It is but natural that they should be partial to open operation, using transurethral manipulation infrequently and with little faith.

Manipulation permits the greatest freedom in technic on the part of the operator, who may improvise to his heart's content. Every one who has mastered the use of the cystoscope has wished for an instrument with which he might safely grasp a calculus and pull it out of the ureter on the spot. To grasp and pull, that is the primitive, the satisfying way of getting a calculus or any desired object, and many ingenious types of forceps have been devised for the purpose. However, because of certain difficulties attending the use of a forceps in the human ureter, no dependable model has yet been constructed.

Briefly these difficulties are as follows:

1. A useful forceps must be rugged in construction, with strong serrated jaws. Yet it must be small and have a semiflexible shaft.

2. Since the forceps must grasp the stone blindly, some provision has to be made to prevent inclusion of the mucosa of the ureter.

3. Granted that these difficulties are solved, a really discouraging fact remains: Only extremely small calculi may be pulled through the ureter. A calculus as large as a 22 caliber bullet if pulled out at one manipulation will likely strip the ureter of much mucosa. Moreover, should a stricture be encountered, an overzealous operator may actually tear the ureter apart.

These observations are not wholly original. However, I did confirm them by a bit of research done some years ago. While engaged in it I became more and more skeptical about the use of a forceps in so delicate a structure as the ureter. In the end I became convinced that I had proved a fact of considerable importance, to wit: It is impossible to pull a calculus out of the ureter with a forceps. This means, of course, that all so-called ureteral forceps are useless. It is true that when the stone is engaged in the meatus and is visible one may deliver it with a forceps. But it is better to do a meatotomy instead.

Lack of space forbids a detailed description of my experiments, performed mostly on large dogs properly anesthetized. The procedure was as follows:

Having exposed and opened the ureters, I implanted calculi of varying sizes and shapes and attempted to

³³ Since the completion of this paper, it has been ascertained that 1 donor was diagnosed as having typhus fever forty-eight hours after he had given his blood, and it was felt that all the bleedings that had been pooled with his blood should be withdrawn. This adds a further loss of thirty six bloods.

Read before the Section on Urology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

grasp them in forceps inserted transvesically from below. I used every type of grasping instrument that the ureter would receive. It was next to impossible to get a firm hold on the stones. On the few occasions when I did succeed a bit of mucosa was invariably included in the bite.

Next, by using one hand to steady the ureter and to manipulate the stone which it contained I was able to get a firm hold on the calculus without including the wall of the ureter. My object was to settle the important question of whether a stone cleanly grasped by a forceps may be pulled out of the ureter. The answer is no. Only the tiniest calculi would respond to reasonable traction, and even they produced serious trauma. Before the medium-sized and larger stones could be moved the ureter would tear.

By interposing a small scale between my hand and the forceps I could measure in pounds how much pull the ureter would take without tearing. All ureters withstood 5 pounds (2.3 Kg.), but none endured a pull of 10 pounds (4.5 Kg.).

Trauma, severe in every case, varied from more or less complete stripping of the mucosal layer to complete division of the ureter.

Having rejected the use of forceps as unsound, I turned to an idea which had occurred to me several years before but which had not been put to the test. It was to loop a ureteral catheter around the stone and use it as a medium for traction.

Fig. 1.—Calculus firmly held within loop. Intermittent traction delivered it in twelve hours.

There were several objections to this procedure. First, was it possible to lasso a foreign body wedged in so small a canal as the ureter? Second, what if success is so complete that having engaged the stone one finds it refusing to budge in any direction? Third, what of the trauma just described? Could it be avoided?

Happily, none of these objections were real. It is not difficult to lasso a stone in the ureter. As to the second objection, in 50 cases I did not encounter a calculus fixed so firmly in the ureter that it could not be dis-

Fig. 2.—Double loop caused by unintentional twist in catheter. Calculus engaged by proximal loop.

lodged. Some trauma was produced, of course, but in no instance was enough mucosa stripped from the ureter to delay recovery.

The technic is rather simple. In all but 5 of the 50 cases the stone was removed with a home-made instrument constructed as follows: A no. 6 F. x-ray catheter, with either a whistle tip or a taper tip, was modified by inserting a silk suture in the distal end, care being taken to tie the knot as small as possible.

A wire stilet should be inserted to stiffen the catheter, which is now ready for use. The catheter with thread attached is passed transvesically to the stone and beyond it if possible. Should it refuse to pass, a local anesthetic is injected and afterward a few drops of liquid petrolatum for lubrication. In nearly every instance the catheter will then pass with little difficulty. However, one will fail now and then in spite of patience and the use of a Blasucci tip. When this occurs one may often succeed by using spinal anesthesia, which does away with spasm as well as most of the pain. Only once in 50 cases was I unable to pass the stone.

If one has succeeded thus far, the thread-bearing catheter is moved on until the renal pelvis is reached. At this point the stilet is withdrawn a few inches and the cystoscope removed, the catheter being left in place. By pushing toward the kidney with the catheter and pulling away from it with the suture one may make a loop without difficulty or injury. There is plenty of room in the dilated renal pelvis. Once the loop has been made, thread and catheter are pulled down the ureter together until the stone is engaged in the loop. No doubt is experienced as to when this occurs, since firm resistance is encountered.

One now is in position to put as much traction as one wishes on the stone, for the loop rarely slips. It is best, I am sure, not to use more pull than 1 or 2 pounds (0.5 or 0.9 Kg.). However great the temptation, one must never try to remove the stone immediately. A small scale is attached to the end of the catheter, the patient is put to bed and pain is controlled by means of an opiate. The nurse is instructed to exert a pull of 2 pounds (0.9 Kg.) on the scale, maintaining it for a moment, every hour or two for twenty-four hours. At the end of that time the patient is given a bit of gas and a pull up to 5 pounds (2.3 Kg.) is made by the physician himself.

In my series of 50 cases the stone was obtained at the end of twenty-four hours in 47. Treatment was continued in the 3 cases of refractory calculi, being successful in 2, in which the stone was passed in thirty-four and forty-two hours respectively. The treatment in the third case was a failure. Having kept the loop in place for seventy-two hours without budging the calculus, I removed it by open operation. Failure was due to the unfavorable relationship of the greatest diameter of the stone to the lumen of the ureter and to the fact that it was actually embedded in the wall of the ureter.

SUMMARY

A new method of extracting ureteral calculi by means of traction is superior to methods now in use in the following respects: (a) A firm grasp on the stone may be had without including mucosa. (b) In contrast to older methods, only one cystoscopic treatment is necessary. (c) It is practically free from danger, provided the simple technic is followed with ordinary care.

134 Pine Street.

ABSTRACT OF DISCUSSION

DR. V. D. LESPINASSE, Chicago: I was interested to hear Dr. Finney's utilization of the loop. As I understand it, he makes his loop in the pelvis of the kidney. That is a neat little technical trick. A similar method was described about five or six years ago in the German urologic literature. The loop in the ureter was made right at the stone. If one is going to do that it must be necessary for the ureter to be large enough to make the turn or for the catheter to be supple enough so that it will not distend the ureter too much. This is the method I have used in five cases. It has worked very well and I have always obtained the stone. I have always checked the size of the ureter by urogram before attempting this procedure and I made various types of loops of various lengths. That is very important. The longer the loop, the larger the ureter must be in which to produce the loop. I have used for a good many years a method of my own concerning which Dr. A. J. Carlson, in commenting on it, said "Lespinasse, that is damned good physiology"; so I call it the physiologic method. I put an obstruction in the ureter and let the ureter dilate above the obstruction until it reaches the size of the stone and then remove the obstruction, and the stone comes down and out. About every six months for many years I have some instruments made to use in the ureter to enable the stone to pass. There is a small multiple curet that one can slide along past the stone, and if the stone has some bumps one can shave or chisel off these rough places, and then the stone will come along much faster. I want to congratulate the doctor on this experience and his experiments: I think they are very fine.

DR. GEORGE R. LIVERMORE, Memphis, Tenn.: I should like to sound a note of warning on intraureteral manipulation. Having been one who devised one of these instruments for the dislodgment of ureteral stones, I wish to go on record as condemning all metal instruments for promoting the removal of stones in the ureter. The ureter is easily damaged, and since

the introduction of American catheters, which are much stiffer than the ordinary catheter that we have been using, I find that puncture of the ureter is becoming much more frequent. Recently Heckel reported 15 cases in which the ureter had been punctured. After an experience of thirty years in urology I had my first puncture of a ureter using one of those stiff catheters. The patient had a stone in the ureter and I was attempting to pass the catheter beyond it. I don't think I have ever been accused of being rough in cystoscopic manipulations but I certainly did not use any excessive force in this case. Perhaps the pressure of a stone produces spots of necrosis or chronic inflammatory reaction and hence the ureter is much more susceptible to damage than otherwise. Dr. O'Connor some years ago suggested the use of prostigmine and reported good results by injecting prostigmine. My results, unfortunately, have not paralleled his. The most important factor, except the damage that may occur, is that one must be sure of the kidney function. If one can get a catheter by the side of the stone, it is much safer to leave the catheter in and drain the kidney rather than try to tie loops in it and pull the stone down. If one pulls on a stone one is apt to tear the ureter or damage its mucosa, irrespective of the experiments on dogs. Spinal anesthesia is another thing that one must be particularly careful of in handling these cases. There is no doubt that it causes relaxation, but it also stops the pain and therefore as my patient did not feel any pain and did not realize perhaps that I was using more force, I was able to push a catheter through the ureter. So please let's get away from intraureteral manipulation with other than soft catheters, leave the catheter in to drain the kidney and promote the passage of the stone and watch the function of the kidney.

DR. HERMON C. BUMPUS JR., Pasadena, Calif.: Dr. Finney should be congratulated on having manipulated 50 stones and encountered serious difficulty only once. This is an unusual record, for in the manipulation of ureteral stones one has the condition of urinary obstruction associated with infection, a combination that can result in the most serious of consequences. Dr. Livermore has emphasized the dangers of rupturing the ureter. I would emphasize those of infection in the presence of obstruction. Severe febrile reaction under these circumstances is likely to occur rapidly as a result of renal involvement, and septicemia not infrequently follows. For this reason it would seem imperative that one should inform the patient of these dangers before attempting manipulation and obtain his permission to resort to the surgical removal of the stone immediately if such untoward symptoms develop.

DR. ROY PELHAM FINNEY, Spartanburg, S. C.: I have to submit to authority in these cases, because you gentlemen have been practicing urology a great deal longer than I have. I did the first few operations with fear and trembling. I would not have undertaken the procedure had it not been for the fact that one gets tired of seeing certain patients once a week and over and over again subjecting them to the pain of "transurethral manipulation." This high sounding term too often means poking and prodding the stone at random. I thought that my loop around the stone would produce an obstruction and acute hydro-nephrosis. To my surprise, none of these cases showed any evidence of obstruction, save 1. On the contrary, the pain in the back was relieved as soon as the loop engaged the stone. This is not remarkable, since the loop acts as a dilator, keeping the walls of the ureter away from the stone. In the 1 case obstruction was complete. Relief, however, was easily obtained when I succeeded in passing a catheter to the renal pelvis without disturbing the loop. When possible I think it is well to do this at the time the loop is applied. I have used Dr. Livermore's instrument. I believe I have tried every instrument that has been devised for extracting ureteral stone. Perhaps I like this one better because it is mine. At any rate, it does work well and I did not get into any trouble in 50 cases. Now and then one may find it impossible to extract either the stone or the loop. What of it? One may be sure that a stone so tightly embedded will respond to nothing short of open operation. One operates. A pleasant surprise awaits you when beginning to feel for the stone. The loop will take one directly to it, especially if an assistant pulls a bit on the distal end.

THE USE OF SULFACETIMIDE IN BACILLARY INFECTIONS OF THE URINARY TRACT

FERDINAND WELEBIR, M.D.

AND

ROGER W. BARNES, M.D.

LOS ANGELES

Recent advances in chemotherapy have been of great benefit in the treatment of infections of the urinary tract. Research in chemotherapeutic agents, especially the sulfonamide compounds, is progressing rapidly. It has been our privilege to have under clinical investigation one of these drugs—sulfacetimide-Schering¹ (*p*-amino-benzene-sulfonyl-acetyl-imide)—which we have used with good results in the treatment of more than 200 cases of infections of the urinary tract due to the colon-aerogenes group of organisms.

In the vast amount of experimental work on sulfanilamide, it was found that it was acetylated in its passage through the body. This acetylation occurs at the amino group in the para position. Vonkennel and Korth² found that sulfanilamide when acetylated at this particular position became nontoxic but completely lost its therapeutic value.

In an effort to develop a compound which would still be relatively nontoxic yet hold its therapeutic effectiveness in the body, Dohrn and Diedrich³ succeeded in removing one of the hydrogen atoms of the sulfonamide group and placing the acetyl group in this position. The structural formula is:

This new compound has been used extensively in the British Empire and in Europe under the name "Albucid"; in the United States it has been under clinical investigation under the name "Sulamyd" (provisionally designated as preparation 338-A). It is supplied in tablets of 0.5 Gm. each.

As with sulfanilamide, the blood concentration and the elimination depend on the solubility and absorption of the compound from the gastrointestinal tract. Sulfacetimide has weakly acid properties owing to the hydrogen of the imido group as a result of acetylation in this position. Consequently, it readily forms easily soluble salts with the alkalis and, therefore, is rapidly absorbed from the gastrointestinal tract. It was found by Karbe⁴ that the average blood concentration during the course of administration (4.5 Gm. a day) was 3.1 mg. per hundred cubic centimeters and that there was

complete elimination of the compound six days after the last dose had been taken. Gertler,⁵ in his determinations, found that the blood concentration reached a maximum of 7.9 to 8.1 mg. per hundred cubic centimeters two hours after the oral administration of a single dose of 4 Gm. of the compound. A slight increase in the blood concentration could be expected during the administration of further doses; but after the drug was discontinued there was a rapid drop in the blood concentration, so that on the third day only traces could be found.

It is eliminated, in a large part unchanged, by way of the kidneys. Kidney function has a bearing on the elimination curve. Gertler reports a steep drop in the elimination curve only after discontinuance of the compound and that by the sixth day after the last dose has been taken the body is practically free of the sulfacetimide, except for possible traces on the seventh day. Dohrn and Diedrich found that approximately two thirds of the absorbed drug appears unchanged in the urine. This possibly accounts for the rapidity with which gram-negative bacilli are found to disappear from the urine.

In our clinical investigation we have used sulfacetimide only in the bacillary group of infections of the urinary tract. Each case presented gram-negative bacilli demonstrated in the urine either by stain or by culture. No value was placed on the *p*_H of the urine, as we found that sulfacetimide was as effective in acid as in alkaline urines. At first the course of treatment consisted of 34 0.5 Gm. tablets given in the following manner: 2 tablets after meals three times a day for three days, then 1 tablet after meals three times a day for two days and ending the course with 1 tablet twice a day for five days. The course lasted ten days. Later we found that a course of 15 Gm. was as effective in the large majority of cases; therefore, those treated toward the end of the series received the reduced dosage. In some cases in which a few bacteria persisted in the urine or recurred, smaller doses were continued over a longer period of time.

Gram stains or cultures and routine urinalyses were done every three or four days after the onset of treatment. This was carried out until from two to five or more negative stains or cultures were obtained. In ten cases frequent determinations of the blood count and hemoglobin changes during sulfacetimide therapy were made (table 1). In 1 case in this group side actions were complained of and in 2 other cases a prolonged term of therapy was required. We observed no tendency to leukopenia or other blood changes in our cases under treatment with sulfacetimide. In cases in which there was a leukocytosis from the infection preceding administration of sulfacetimide we noted a reduction to a relatively stationary level, and this continued throughout the course of treatment.

This report covers a series of 200 cases. Fifty-four additional dispensary cases in which initial complaints were limited to the bladder are not reported, for in these cases the patient failed to return after receiving the tablets; and it is probable that most of them received sufficient relief from their symptoms to make them feel that there was no need for further treatment. The drug was given each patient when gram-negative bacilli were found in the urine. Cystoscopy and a study of the kidney were done on the patients whose

no definite evidence of other disorder and (2) those in whom a pathologic condition in addition to an infection of the bladder was demonstrated. The patients listed in table 2 are those included in the first group. Many of them probably had a low grade infection of the upper urinary tract. With a few exceptions, the patients who are classified as "recovered" received only one course of treatment, whereas those who are classified as "improved" or "unimproved" required repeated courses or continuation of small doses of the drug to

prevent recurrence. It may thus be concluded that if recovery is to occur in a patient placed on this form of treatment, the first Gram stain taken three or four days after the onset of administration of the drug will give a relatively accurate prognosis. Some patients tolerated only small amounts of the compound yet

recovered on these smaller doses. The average dose for recovery was 17.4 Gm., the maximum dose 40.75 Gm. and the minimum dose 4.75 Gm. The average number of days required for recovery was ten and two-tenths, the maximum twenty-seven and five-tenths and the minimum five days.

Three side actions were noted during the administration of sulfacetimide in this group:

CASE 1.—A woman aged 32 complained of mild nausea, vomiting, dizziness, "inward trembling" and precordial palpitation, beginning four days after onset of therapy, a total of 10.5 Gm. having been given. The symptoms were so mild, however, that the drug was continued until she had taken 17 Gm. Immediately after completion of the course of treatment all symptoms disappeared, and on repeated Gram stain of catheterized specimens of urine no recurrence of the infecting bacilli was found.

CASE 2.—A woman aged 34 complained of a maculopapular itching rash covering the neck, chest and lower portion of the face which occurred on the second day of therapy after a total of 4 Gm. Medication was discontinued and the rash gradually improved and completely disappeared five days after its appearance. A similar reaction had been experienced with

low sulfanilamide dosage. The urinary infection cleared up and subsequent specimens remained sterile.

CASE 3.—A woman aged 62 noticed on the second day of therapy, after a total of 4 Gm., an itching erythematous rash which appeared on the face and arms and also was distributed irregularly over the body. The drug was discontinued, and there was complete disappearance of the rash in four days. Repeated Gram stains of urine specimens remained negative.

The second group (table 3) comprises 105 cases diagnosed as acute or chronic cystitis in which the pathologic condition producing the infection was definitely diagnosed. These complicating factors were acute or chronic pyelonephritis, hydronephrosis due to ureteral stricture, benign hypertrophy of the prostate, chronic prostatitis, ureteral and renal calculi; carcinoma of the prostate and pregnancy complicated by pyelonephritis. Of these, 84, or 80 per cent, recovered; 18, or 17.1 per cent, showed definite improvement, and 3, or 2.8 per cent, were not benefited by the drug. Five patients had reactions. The average dose for recovery was 28.1 Gm., the maximum 52 Gm. and the minimum 8 Gm. The average length of time before recovery occurred was eleven and seven-tenths days, the maximum thirty-four days and the minimum four days.

In this group of infections of the combined upper and lower urinary tract, 20 patients received renal pelvic lavage in conjunction with sulfacetimide orally. Fourteen, or 70 per cent, of these patients recovered and 6, or 30 per cent, showed improvement. A group of 48 similar patients with infection of both the upper and the lower urinary tract received no therapy except the oral administration of sulfacetimide. Of these, 36, or 75 per cent, recovered and 12, or 25 per cent, showed improvement.

The 5 cases of side actions which occurred in group 2 are as follows:

CASE 4.—A man aged 66 had a bladder infection after transurethral resection for benign hypertrophy of the prostate. The patient was greatly debilitated and was a poor surgical risk. A total of 65.5 Gm. of sulfacetimide was given over a period of eighteen days. Nine days after the first dose he complained of an increase in the pulse rate, pain and depression about the precordial area. The dose was reduced from 0.5 Gm. three times a day to 0.5 Gm. twice a day, which lessened the symptoms; two days after the last dose had been taken all

course was repeated in smaller doses, but the rash immediately reappeared in the same areas. There was complete disappearance of the rash three days after the last dose had been taken.

Case 8 is reported in detail because of its interesting character:

CASE 8.—A man aged 34, with chronic pyelonephritis and chronic cystitis due to renal and ureteral calculi, had had severe reactions following the oral administration of sulfanilamide, the chief manifestation being a rash. The dosage was reduced but the rash would persistently reappear, no matter how small the amount given. He was then placed on a course of sulfacetimide. A two week rest period followed; during this time there was a constant shower of gram-negative bacilli in the urine and a recurrence of the costovertebral pain and symptoms of cystitis. At the end of this period he was started on a second course. On the second day he complained of mild cyanosis, dyspnea, general malaise and rash about the corona of the glans penis. The medication was discontinued and five days later there was no sign of the reaction.

The urine became crystal clear during administration of the sulfacetimide, and there was no evidence of the infecting

TABLE 4.—Reactions

Case	Sex	Age	Diagnosis	Grams Taken Before Reaction	Day Reaction Was First Observed	Total Grams Taken	Total Days Treated	Reaction	Comment
1	♀	32	Acute cystitis	10.5	4	17	5	Nausea, vomiting, dizziness, palpitation	Medication discontinued; reaction disappeared
2	♂	66	Chronic cystitis, benign prostatic hypertrophy, chronic prostatitis	16.5	8	26.5	16	Increased pulse rate, pain and precordial depression	Reaction disappeared when medication was discontinued; similar reaction with sulfathiazole
3	♀	23	Right pyelonephritis	8	4	8	4	Nausea, palpitation	Reaction disappeared two days after medication was discontinued
4	♀	39	Chronic cystitis and pyelonephritis	12	5	13	7	Erythematous rash on trunk and feet	Medication discontinued; rash disappeared five days later
5	♀	55	Cystitis, hydronephrosis	8	4	80	80	Nervousness, palpitation	Dosage reduced to b. i. d. caused less nervousness, medication continued until patient improved
6	♂	34	Ureteral calculus, chronic pyelonephritis	6	2	21.5	34	Mild cyanosis, dyspnea and malaise	Dosage reduced; reaction disappeared
7	♀	34	Chronic cystitis	4	4	4	2	Maculopapular itching rash on feet, neck and chest	Disappeared five days after medication discontinued; had same type rash with sulfanilamide; recovered from cystitis
8	♀	62	Chronic cystitis	4	2	4	2	Erythematous rash on face, arms and body patches	Medication discontinued; rash disappeared four days later; recovered from cystitis

symptoms of reaction disappeared. The patient complained of the same symptoms while he had been given sulfathiazole.

CASE 5.—A man aged 23 had pyelonephritis on the right side. The patient complained of nausea and palpitation when sulfanilamide was administered. He was started on 0.5 Gm. of sulfacetimide four times a day, and after he had taken it four days he complained of mild nausea and palpitation. The drug was discontinued and two days later there were no signs of reaction. He recovered from the infection and has remained well without further treatment.

CASE 6.—A woman aged 55 had infected hydronephrosis and cystitis. The patient had previously complained of nervousness, palpitation and malaise when sulfanilamide and sulfathiazole were administered. With the administration of the mandelates a rash developed. Four days after starting sulfacetimide she complained of nervousness and palpitation. She had taken 8 Gm. during this time, and the dosage was then reduced to 1 Gm. daily. The palpitation disappeared and there was a striking decrease of the nervousness. The patient continued therapy until there was a distinct improvement.

CASE 7.—A woman aged 39 had chronic cystitis and chronic pyelonephritis. Five days after the first dose of sulfacetimide, and after she took a total of 12 Gm., a mild erythematous rash developed on the trunk and feet. The drug was discontinued and five days later there was no evidence of the rash. The

bacilli. Immediately after discontinuance of the drug the urine became cloudy, and gram-negative bacilli were found.

A few days after all signs of the reaction had disappeared, the patient was placed on 0.125 Gm. twice a day. There was immediate and absolute relief from all symptoms, and the urine immediately became clear and sterile. The dosage was then increased to 0.25 Gm. twice a day, whereupon the entire group of symptoms reappeared and the former reaction recurred. The dosage was again lowered to $\frac{1}{4}$ tablet twice a day and the patient was without symptoms. After two months of the smaller dosage all medication was discontinued, and repeated examinations of the urine have shown no evidence of the previous infection, either by Gram stain or on culture.

In the entire series of 200 cases, we had 8 instances, or 4 per cent, of side actions (table 4). Five, or 62.5 per cent, had similar side actions with sulfanilamide or sulfathiazole. One patient noticed the first signs of reaction on the eighth day, after a total of 16.5 Gm. In 4 cases the reaction appeared on the fourth day, in 1 case on the fifth and in 2 cases on the second day. The average time before symptoms appeared was four and one-tenth days. The average amount of drug given before the reaction appeared was 10 Gm. One patient had neuritic symptoms with sulfanilamide, but when

medication was changed to sulfacetimide she had none. Three patients could not tolerate either sulfanilamide or sulfathiazole but had no ill effects from sulfacetimide.

Seven patients with acute pyelonephritis of pregnancy were treated. All were given an eight day course of 30 tablets (15 Gm.). In each case the urine became sterile three days after treatment was started, and after the course was finished the patients required no repetition of sulfacetimide. Chills, fever and pain disappeared immediately after the first day. Repeat stains of urinary sediment have all been negative, and deliveries have been uncomplicated. Two other patients treated post partum, and 1 after cesarean section, recovered.

Three children are included in this series. One child aged 5 years had been treated with mandelates, sulfanilamide and intramuscular azosulfamide with no reduction of the temperature nor elimination of the chills and fever. A dose of 0.25 Gm. of sulfacetimide was given twice a day for two days, and the course was completed with 0.25 Gm. once a day for five days. The chills, fever and costovertebral pain disappeared on the third day. The urine became sterile—after having had many pus cells and gram-negative bacilli for four months—and remained sterile on repeated examinations over a period of nine consecutive months. Two patients, each 10 years of age, recovered from acute attacks of infection of the lower part of the urinary tract with the administration of sulfacetimide and have been without symptoms for eight months.

In this group of 200 patients we found that 21 had been on sulfanilamide before sulfacetimide was given. Sulfanilamide was discontinued, either because of no response to the drug or because of reactions. After treatment with sulfacetimide, 17 patients were classed as recovered, 3 showed improvement and 1 did not respond. This is an 80.9 per cent improvement over sulfanilamide. Eleven patients who did not respond to the mandelates recovered with sulfacetimide, while 4 did not respond—a 73.3 per cent improvement over the mandelates. Three patients who did not respond to azosulfamide recovered on sulfacetimide therapy.

TABLE 5—Summary

	Number	Per Cent
Total number of cases	200	100.0
	171	85.5
	25	12.5
	4	2.0
Reactions	8	4.0

Six patients had previous sulfathiazole therapy: 2 could not tolerate it and 4 did not respond to it. These 6 patients recovered when placed on sulfacetimide therapy. Nine other patients who had taken some other form of oral therapy without response recovered when placed on sulfacetimide therapy.

SUMMARY

Two hundred cases of bacillary infection of the urinary tract were treated with sulfacetimide. The percentage of recoveries was 85.5; 12.5 per cent showed improvement and 2 per cent showed no response to the drug.

Sulfacetimide has been more effective in the treatment of these infections of the urinary tract than has sulfanilamide and the mandelates. In 80.9 per cent of the sulfanilamide-resistant cases recovery occurred when sulfacetimide was given; in 73.3 per cent of the mandelate-resistant cases and in all of the sulfathiazole-resistant cases recovery occurred.

There were toxic reactions in 4 per cent of patients in this series. After discontinuance of the drug, the reaction disappeared within a period of from one to six days.

The results of this clinical investigation show that sulfacetimide is effective and superior to other sulfonamides in the treatment of bacillary infections of the urinary tract.

312 North Boyle Avenue.

THE CHEMOTHERAPY OF GONORRHEAL URETHRITIS IN THE MALE

WILLIAM BROMME, M.D.

DETROIT

No group of therapeutic substances has gained such rapid and universal utilization as have the sulfonamides. It is undoubted that their advent has been the important therapeutic accession of the decade and that the control of many diseases caused by infectious agents now has been brought within the physician's grasp. It is equally true that there has developed a degree of uncertainty relative to the specific indications for the use of the sulfonamides, and in no part of the literature is this more evident than in the discussions of the treatment of gonococcal infection in the male.

Before the advent of the sulfonamides, how was gonorrhea cured? A host of chemicals and dyestuffs was given orally, first one and then another when the first seemed not to accomplish the desired result. A veritable flood of colored solutions was instilled onto the urethral mucosa or washed over its surface. Various vaccines were prepared from laboratory culture of strains of the organism. The human body containing the organism was exposed to high temperature. And time itself often cured the disease in those who put not their faith in doctors.

There is evident the same confusion today. There is one group of observers¹ which believes that sole reliance should not be placed on the sulfonamides but that the therapies once considered curative in themselves should be supplemented by the cautious use of these newer chemicals: this point of view bears consideration because of the extravagant claims proposed for other drugs which did not bear the test of time. A second group² holds that the risk of toxic symptoms from the use of the sulfonamides exceeds any possible benefit to be gained from them. The third, and by far the largest group,³ has observed the phenomenal and rapid cure of gonorrhea when the sulfonamides alone have been used, and series with cure rates as high as 96 per cent have been presented in evidence.

Pelouze⁴ recognized this uncertainty, and his statements made in 1928 are still valid:

A study of the disease gonorrhea will show that from the standpoint of pathology it holds a rather unique position among diseases. In other diseased conditions the question of pathology has held a large part of the field, so that before one considered the disease itself, he spent much time upon the pathology of it. With gonorrhea it has been entirely different. Though the pathologic picture has been a well completed one for at least twenty-five years, it has been lost sight of almost entirely in our considerations. Such a state is hard to understand, for there is no disease that can vie with gonorrhea in the survival of things which should have disappeared from its literature. No group of writers has been followed longer than those who early wrote upon gonorrhea. Indeed, it might be said with much truth that, if our grandfathers and possibly great grandfathers in medicine could come back and read what we have to say regarding the disease today, they would feel much at home. They would be little surprised over what we have added to their store of knowledge. Indeed, they would probably say that we have added little and lost much.

It seems well to review the nature and extent of the infectious process in the urethral wall:

The weight of evidence apparently shows that the mode of extension of the disease is by the surface progression of gonococci and not by subsurface transmission. Though it is a disease of surface penetration, it is apparent that this occurs perpendicularly to the surface. The bacteria pass between the epithelial cells into the submucosa, often as deeply as the trabeculae of the corpus spongiosum. . . . The speed of the penetration is great, so that by the end of thirty-six hours, they are well in the deeper submucosal spaces.⁵

In other words, this is a disease of the total urethral wall and not of the urethral surface. There is remarkably little evidence that any substance instilled onto the urethral mucosa ever cured gonorrhea except as an accessory to time or through nonspecific chemical stimulation. One recalls the classic report⁶ of the series in which a solution of tincture of capsicum was compared favorably with a 5 per cent solution of silver nucleinate: "The results were equally as good in this group of patients as were those obtainable in a like class of patients by the use of any germicide."

Neither in those days nor in this day can the surface application of an antiseptic to the urethra be considered curative. It seemed to me that valuable experience and perhaps a valid conclusion could be drawn from the exclusive oral use of one of the sulfonamides. To that end this series of 100 cases was prepared and is presented herewith

DRUG USED

Sulfathiazole (2-sulfanilamido-thiazole) was the sulfonamide used in this series. It appeared to be the derivative of choice in the treatment of gonococcal urethritis in the male⁷ on the basis of lessened risk of toxic

reaction and high therapeutic efficiency, although the more recent pyrimidine substitution form sulfadiazine may prove to be equally efficient.⁸

AGE AND OCCUPATION OF PATIENT

The average age of the group of 100 patients was 28 years. The oldest was 46 and the youngest was 22.

These men were employed in the heavy industries in which the expenditure of physical energy is great. It was desirable that none lose time from their work because of intercurrent infection.

PREVIOUS INFECTION

Forty per cent of the series had experienced one or more previous attacks of gonococcal infection. This factor is noted in an attempt to discover whether or not there remained any point in following the dictum that one attack so changes the epithelial character of the urethra that subsequent attacks bear a different clinical pattern. No such correlation was observed.

ONSET OF SYMPTOMS

The evidence of urethral irritation appeared uniformly four days after exposure. This is the general incubation period for the common strains of the organism. The fact that 36 per cent of the series had used samples of the host of commercial prophylactics and yet contracted the infection defies critical analysis

PREVIOUS SULFONAMIDE THERAPY

Thirty-six per cent of the group had received treatment with sulfanilamide before they became part of this series. The dose of sulfanilamide had ranged from 1 to 3 Gm. daily and had been continued from seven to forty-nine days without alteration of the clinical evidence of the disease. The total dose of sulfanilamide involved ranged from 9 to 49 Gm.

CRITERIA OF INFECTION

In every case there was present a urethral discharge in an inflamed, edematous urethral canal. Stain of the urethral discharge revealed gram-negative intracellular diplococci in all cases. The first glass of urine was cloudy or turbid in all cases. The second glass of urine was cloudy or hazy in 70 per cent, indicating, traditionally at least, posterior urethral involvement. All were cases technically of acute gonococcal urethritis. The prostatic fluid presented a significantly increased cell count in 35 per cent of the cases, and the organism was identified in smears of the prostatic fluid in 15 per cent of the total series.

DOSAGE OF SULTATHIAZOLE

The total initial daily dose varied between 3 and 7 Gm., the average approximating 4 Gm., which was the actual daily dose for most of the series. This daily dose of 4 Gm. was divided in four parts and given at approximately equal intervals during the hours of the patient's activity. This dosage was maintained from two to eight days, the average being somewhat less than five days until cure was attained, although the same dosage was maintained from one to two days after evidence of the disease had disappeared. The average total dose for this period was 18.4 Gm.

Forty per cent of the series required no further sulfathiazole because smears had become negative within

this period and had remained negative for a thirty day period of observation following the first negative smear. On the average, negative smears were obtained within three days on 4 Gm. daily.

Sixty per cent of the series required further doses of sulfathiazole for cure, and the average additional amount of the drug was 8.2 Gm., which represents slightly more than two days of additional medication. One half of this group represented patients who had received sulfanilamide previously. The smallest dose of sulfathiazole received by any patient was 9 Gm. and the largest 33 Gm.

CRITERIA OF CURE

The diagnosis of cure was based on (1) inability to find a urethral discharge for staining purposes and (2) persistently negative culture of the urine in the face of traditionally provocative tests. In all cases the ingestion of alcohol was utilized as a provocative measure and, in quite a number, protected coitus (and I suppose in a certain number unprotected coitus). In a few instances a steel sound was passed, but in no instance was an irritating chemical instilled into the urethra. The utilization of these traumatizing procedures is a part of the historical past of the treatment of gonococcal infection in the male.

RESULTS

The period of actual therapy and close observation included a period of three to thirteen days, and in this time 100 per cent of the series was cured. All were observed for an additional thirty day period. There was no increased period of treatment for those who had previously had a gonococcal infection. The 36 per cent who had previously received sulfanilamide and were transferred to sulfathiazole without a waiting period were cured with the same average amount of sulfathiazole and within the same period as those who had had no experience previously with the sulfonamides. There were no incapacitating reactions and no complicating sequelae of the disease.

COMPLICATIONS

The complications observed in the modern management of acute gonococcal infection in the male are of two types. The first derives from the tendency of the disease to spread centrally to involve the prostatic urethra, prostate gland, seminal vesicles, vasa, epididymides and the deeper para-urethral structures. This tendency is an inherent one in the disease; it can occur spontaneously but it has been demonstrated repeatedly to occur more frequently when the pressure of retrogradely injected material exceeded the ability of the tissues to oppose that force. Since no local medication was utilized in this series, and since the organism had disappeared in a reasonably short period of time, it was not at all surprising to find that there were no local complications of the disease and no reason to anticipate the development of stricture in the future. Three patients (3 per cent) presented prostatic fluid cell counts in excess of the normal range, but culture of the fluid was negative for gonococci one month after the patient had been declared cured by standard criteria. I am not certain that these patients had not possessed a nonspecific prostatitis antecedent to their acute gonorrhea. At all events, they did not have a gonorrheal prostatitis. There were no complications involving hematogenous spread of the organism.

There is a second series of complications related to the administration of the drug. The literature has described dermatitis,⁹ nausea, vomiting, headache, dizziness, hematuria, oliguria or anuria and anemia. These signs seem to be associated in variable degree with the administration of all sulfonamides. There seems to be no relation between either the dosage or the duration of treatment and the appearance of one or many of the toxic reactions to the drug used. In this series 23 per cent of the patients complained of variable nausea, but there was no vomiting. Five per cent manifested elevation of temperature with a recorded peak of 100.6 F.; these were all men who had received sulfanilamide previously, and the fever appeared toward the end of the course of intensive 4 Gm. daily of sulfathiazole. In 1 patient a diffuse, discrete, pruritic, papular cutaneous eruption developed which ultimately was demonstrated to be scabies. There were no instances of hematuria, oliguria, anuria or suggestion of tubular blockage by crystallization of the excretion product in the kidney. I had been influenced by the work of Curtis,¹⁰ which suggested that a prime factor in the maintenance in solution of the excretion product was an alkaline urine and, accordingly, I ordered for the entire series the concurrent administration of a urinary alkalizer (a citrate) orally. Likewise, the experience of Wilson at the Children's Hospital of Michigan¹¹ with regard to maintenance of an adequate volume of fluid intake was accepted, and all in this series were urged to force fluids to capacity. Marshall⁸ has noted that the urine of nearly every patient placed on sulfathiazole therapy will show quantities of crystals of acetylsulfathiazole if it is kept iced for four hours. I observed no crystallization in the freshly voided urine and felt that the combination of alkalinized urine of moderate dilution was a safeguard against crystallization of the excretion product within renal tubules.

No patient lost time from work. A few noted transient headache but were not incapacitated by it.

COMMENT

This series did much to convince me that there has developed a needless confusion in the minds of those who treat acute gonococcal infection in the male. This might well be a time to revise the program of treatment to exclude those things which have been done traditionally and which apparently have no further justification for their perpetuation. With the advent of a series of drugs, of which sulfathiazole is the current example, which are in themselves capable of curing gonococcal infection, there seems to be little justification for the continued use of other routines in conjunction with the sulfonamides, especially when the time limit to achieve cure on sulfonamide therapy is infinitely shorter than with any other known therapeutic agent. Why must one run the rainbow of colors in dyestuffs and percentage strengths of silver proteinate in the archaic procedure of instillation onto the surface of the urethral mucosa when the active infection is far deeper than will ever be reached by this method? Why is this routine perpetuated which is not based, after all, on an understanding of the pathologic nature of the disease? One can filter into those tissues which harbor the gonococcus a medication which is lethal to it. Nesbit has shown that the action of the drug is

in the tissues and not in the excretion products eliminated in the urine.¹²

The complications observed in this series were in no sense critical or disabling and offered no contraindication to continuation of therapy. The literature does report high temperature, extensive dermatitis, conjunctivitis and evidence of renal interference, and had these appeared in my series I probably would have discontinued the drug. But the weight of evidence is that these manifestations of intolerance by the patient come late in the course of protracted therapy.

I have a feeling that the dosage must be high from the start. There is no justification for a dosage schedule which tends to start at a low level and then builds up to what is known to be an adequate dose. If there is anything to the notion that organisms can become tolerant to a chemical so that they become resistant ultimately to its action, there is no better method of inducing this unfortunate state than by trying out inadequate doses initially. I suspect that what are called "sulfonamide-resistant" strains of organisms have become so by virtue of the use of too cautious dosage. As a matter of fact, the 36 per cent of this series who had been exposed to sulfanilamide without therapeutic response and were thus to be considered "sulfonamide resistant" were placed without a rest period on adequate doses of sulfathiazole and were cured at exactly the same rate and with the same average doses as those who had not received a sulfonamide previously. Thus I cannot take too seriously this matter of alleged induced resistance to the drug without wondering what might have happened if the dose of the drug had been within the range of actual therapeutic efficiency.

A word of comment is in order regarding the matter of the evaluation of the progress of therapy through repeated determinations of the blood level.¹³ Through the first third of the series I studied examinations of the blood level only to find a wide variation in the reports. It soon became evident that I was not altering the dose of the drug in those whose blood level was lower or higher than the average. It became equally obvious that the interpretation of clinical conditions meant considerably more in the management of each case. There was no instance in which the summation of clinical signs proved undependable, and with the wealth of information to be gained from the study of the urethral discharge and the urine I abandoned further routine determinations of the blood level as a thoroughly unnecessary additional expense to the patient.

Finally, it must be remembered that there has always been a sharp increment in the incidence of the venereal infections with the congregation of large numbers of our youth in cantonments. Unlike 1917, the physician has at his disposal a drug which is a safe, speedy, non-traumatizing and certain treatment for gonococcal infection in the male. With this form of management of the infected, the physician's experience should be much happier than it was during the first World War.

CONCLUSIONS

1. Sulfathiazole is capable of curing gonococcal urethritis in the male quickly when administered orally in doses of 4 Gm. daily. This dosage should be continued for a time after there is clinical and bacteriologic evidence of cure.

2. On this dosage, the appearance of complications due to drug toxicity are rare and should not impel one to shun the drug.

3. The estimation of the blood level in the face of easily obtained clinical evidence is an unnecessary procedure.

4. Traditional adjuvant routines of therapy are not necessary.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. WELEBIR AND BARNES
AND DR. BROMME

DR. EDWARD NOBLE COOK, Rochester, Minn.: I was impressed with the fact that the dosage used by Drs. Welebir and Barnes is not excessively high. Many of us found that the 75, 90, 120 and 150 grain (5, 6, 8 and 10 Gm.) doses daily were not necessary. Drs. Welebir and Barnes have found that a dosage of 20 to 30 or 40 grains (1.3, 2 or 2.6 Gm.) a day will take care of most of these infections. I have found that in the simple bacillary infections confined to the bladder the percentage cure rate is high. Even though the involvement may extend to the kidneys, provided there is not extensive pathologic change, the percentage cure rate is little changed. I might take exception to what Drs. Welebir and Barnes stated with regard to comparing sulfacetimide with mandelic acid or some of the other sulfanilamide compounds. All have had the experience in which we have used one or two courses of sulfanilamide and then given it a third time and, much to our surprise, eradicated the infection without a great deal of difficulty. I was interested in the fact that 70 per cent of Dr. Bromme's patients, when they first came to him, had posterior involvement. Yet the cure was just as high in this group as in the group without posterior involvement. He too has found that a medium sized dose is sufficient, that the 75 to 120 grain (5 to 8 Gm.) doses have not been necessary. In his series there have been no complications. In a small group of patients I have not seen complications. It is rare now to see a gonorrheal epididymitis or a periurethral abscess. The economic value of these drugs can only be estimated, but it must run into millions of dollars when one considers the time and the effort saved. Dr. Bromme has called attention to the importance of the clinical observation of the patient. I have found much the same thing. The blood concentrations aren't necessary; if one will see the patient every day or two one will not have to resort to all of these tests, which increase the cost of care to the patient and do little as far as his ultimate recovery is concerned.

DR. EDWIN PASCAL ALYEA, Durham, N. C.: In Dr. Bromme's paper one finds still another proof of the efficacy of sulfathiazole in the treatment of gonococcal infections. His cure rate is 100 per cent. I wish we had the "Detroit strain" of gonococcus in North Carolina. In 1937 it was shown that large doses of sulfonamide drugs and high blood concentrations were not necessary for a cure in gonorrhea. Since then this has been verified many times. Recently Mahoney reported a large series of cases treated with sulfathiazole; one group received 2 Gm. a day; another group received 4 Gm. a day; the cure rate, 90 per cent, was exactly the same in the two series. The adequacy of Dr. Bromme's therapy should be questioned. As is shown by his own series, 60 per cent of those stopped in forty-eight hours needed further treatment. I favor the following scheme of therapy: Three Gm. of sulfathiazole is given the first day and 2 Gm. a day thereafter for nine days. If, after the fourth day, there is no response, the drug is switched to similar doses of sulfapyridine. This is given for seven days. If there is no response to sulfapyridine in four days, switch to sulfanilamide or discontinue sulfonamide therapy. As to criteria for cure, in addition to Dr. Bromme's recommendations I think it is necessary that prostatic cultures be made every two weeks until at least four negative cultures for gonococci are obtained. In addition to this, patients should have the "probable cure"; namely, (1) no urethral discharge for two months; (2) four

prostatic secretions, examined one week apart, to have not more than ten leukocytes per high power field, and stained smear negative for gonococci; (3) four urine specimens one week apart, first glass clear, no leukocytes in centrifuged microscopic test and no gonococci in the stained smear. Drs. Welebir and Barnes state that in the complicated cases the dosage must be raised for cures. My associates and I did not find that such augmentation, in the case of the other sulfonamide drugs, increased our cures. If the complication present was not first treated, they have indeed a high percentage of cures, 80 per cent, much higher than we and others have obtained with any of the other sulfonamide drugs. As for the uncomplicated cases, their 91 per cent cures are slightly higher than we obtained with sulfapyridine for the treatment of colon bacillus infection, 88 per cent, and considerably higher than sulfathiazole, 77 per cent, and sulfanilamide, 80.6 per cent.

DR. W. RAY JONES, Seattle: There is a reason for the failure of sulfonamide therapy seldom considered; pus and exudate contain a substance which will neutralize the action of the drug in a greater concentration than it is possible to get the sulfonamides in solution. Hence, if there are focal abscesses, there must be recurrences when these open and drain. To illustrate, here in the gross is an infection of the paraurethral glands, the female prostate with a pouting meatus, and so on. This case developed during sulfonamide therapy for gonorrheal urethritis. The various crypts and follicles may become infected and a closed abscess result. The suburethral glands likewise may serve as foci to be uninfluenced by sulfonamide therapy until evacuated. My plea is to examine carefully for all possible nondraining infected areas before pronouncing the patient cured, else an unexplained recurrence will probably result due to infection of these various crypts and follicles.

DR. VICTOR D. LESPINASSE, Chicago: The highest possible concentration of drug should be obtained in the location where the bacteria are. The drug can be placed in the mouth or injected into the veins and it goes into the blood stream, but if it is injected into the urethra as well the drug will be on both sides of the organism. It surrounds the organism and engulfs the organisms in the urethral cavity. Nobody can deny that they are there; and there is no irritation from these drugs. My plea is to inject into the urethra as strong a solution of sulfathiazole or sulfanilamide as is possible to make in water in addition to use of the drug by mouth. I think that the results will be better than they are if one limits oneself to the use of the drug by mouth, subcutaneously or intravenously.

DR. WALTER M. SIMPSON, Dayton, Ohio: My associates and I have encountered an apparently irreducible residue of therapeutic failures, even with sulfathiazole. In our experience, based on rigid bacteriologic criteria, about 12 per cent of patients with gonococcal infection fail to respond successfully to presumably adequate sulfathiazole therapy. In a paper published in *THE JOURNAL*, February 1, we described a procedure directed toward the rapid elimination of such refractory gonococcal infections by the utilization of a single session of artificial fever combined with chemotherapy. It was found that any of the sulfonamide drugs (sulfanilamide, sulfapyridine, promin or sulfathiazole) given concurrently with therapeutic fever had no advantages over fever alone. We concluded that there is a latent period in the action of the sulfonamide compounds, the average of which is about eighteen hours. Therefore, in order to obtain the maximum response to the single fever treatment it is necessary to give the drug in reasonably high doses for eighteen hours prior to the fever session. In the report in *THE JOURNAL* we suggested a ten hour session of fever at 106.6 F. Our more recent studies, soon to be described in *War Medicine*, reveal that with sulfathiazole or promin given eighteen hours prior to a single fever session it is possible to reduce the number of hours of fever to eight and to reduce the rectal temperature level to 106 F. Thus far, such a combined program has resulted in 100 per cent elimination of the disease in chemoresistant cases. What was looked on as a technical feat a decade ago as regards the administration of fever therapy can now be prescribed with a regularity which approaches routine, owing to the remarkable improvements in the technics and in the apparatus for fever therapy. We are particularly interested in the relation of this

procedure to military medicine. We feel that the stated mission of the United States Navy, "to keep as many men at as many guns as many days as possible," can be fulfilled as regards resistant gonococcal infections. The period of hospitalization necessary for this combined method of treatment is forty-eight hours. We feel, therefore, that if this procedure is surrounded by the necessary safeguards as regards well trained personnel and efficient apparatus it provides a simple, safe, cheap and certain method for the eradication of the gonococcal infections known to be refractory to the chemotherapeutic agents now available.

DR. ROGER W. BARNES, Los Angeles: As many urologists have probably used sulfacetamide, I wish to say a word to identify it more clearly. It is preparation 338-A, Schering, the chemical name which has been accepted being sulfacetamide. The term "Sulamyd" is Schering's trade name, and it was the Medical Research Division of Schering Corporation which supplied us with the drug we used. It is not as yet on the market because it has not been passed by the Food and Drug Administration, but it probably will be on the market in a few months. Of the eight reactions in this series of 200 cases, all were mild, and we did not have to hospitalize any patients with reactions. In 4 of them the drug was discontinued, and in 4 others, when the dosage was reduced, the reactions became less, so the medication was continued until the original infection was controlled. Dr. Alyea remarked on the higher percentage of recoveries which we reported from the use of this drug than he had obtained from other sulfonamides. I believe that all urologists will find this to be true when they use it in bacillary urinary tract infections. We found it to be less efficacious in clearing up coccic infections than sulfathiazole and sulfapyridine. In fact, in a number of cases in which there were mixed infections we found that the gram negative rods cleared up with the sulfacetamide, whereas the coccic infections did not. I believe that cystoscopy and a kidney study are not necessary in every case in which there is pus in the urine. Many of these cases will clear up without this manipulation, and in 95 of the cases in our series, studies of the upper urinary tract were not made. Only in the cases in which the infection persisted or recurred was more thorough study made. The cases in the second group, "cystitis with complications," included all in which there was another pathologic condition besides the infection. In these the complicating pathologic condition was treated while the drug was being given. The patients whose infection cleared up and who remained well after the drug was given and the complications removed were counted as recoveries, whereas if for some reason the complication could not be treated and the infection cleared up with the use of the drug but then recurred they were listed as improved. There were 12.5 per cent improved in this group and most of these cases were those in which the infection cleared up originally and then recurred after the medication was stopped.

DR. WILLIAM BROMME, Detroit: I think Dr. Cook and Dr. Alyea and I see eye to eye with regard to the premises that these drugs can kill the organism and that we no longer have to place medications in the urethra to cure the disease. But I do not believe the daily dosage of 3 Gm. is adequate. With that amount we shall see complications and a protracted clinical course. The dosage must be large from the start and kept large until there is bacteriologic evidence of cure. I am glad that Dr. Alyea repeated the necessity of meticulous supervision of details and bacteriologic control. I was much stimulated by Dr. Ray Jones's demonstration in the Scientific Exhibit. I see no gonorrhea in females, but I think we must assume from now on that, when glands do not drain and when periurethral abscesses form, something has gone wrong with our basic therapy. When we do not administer sufficient drug to overwhelm the organism we must anticipate the development of undrained areas which will require, as they have in the past, a mechanical method of drainage. Dr. Lespinasse's remarks about large doses is the bedrock of the whole story. No case in my series required fever therapy and I am unable to comment on Dr. Simpson's extensive experience with this adjuvant therapy. His dosage of sulfathiazole approximates the dosage which was curative in a large part of my series.

THE USE OF COTTON AS A
SUTURE MATERIALWITH PARTICULAR REFERENCE TO ITS
CLINICAL APPLICATIONWILLIAM H. MEADE, M.D.
EAST LANSING, MICH.

AND

CARROLL H. LONG, M.D.
NEW ORLEANS

Fundamentally, surgeons are interested in methods and materials which lead to primary and early wound healing. Dissatisfaction with the results obtained with catgut as a suture material has led to a renewal of interest in nonabsorbable sutures during the past decade. After Bulloch and his co-workers¹ in Great Britain, Kronig² in Germany and Meleney and his associates³ and Clock⁴ in this country had demonstrated that catgut purchased on the open market was not infrequently contaminated, Whipple,⁵ who had previously used catgut, strongly advocated the use of silk, with which he was able to show a reduced incidence of infections in clean wounds. This work gave a new impetus to the use of nonabsorbable suture material, a usage initiated in modern surgery by Halsted⁶ and Kocher⁷ at the end of the last century.

There exists venerable authority for the use of cotton as surgical sutures in Suśruta's recommendation of cotton for the suture of wounds of the abdomen and joints about 500 B. C. Gage⁸ and Guerry⁹ have employed fine cotton for ligatures on an empiric basis for many years. In 1939 Meade and Oschner,¹⁰ in a previously reported exhaustive experimental study, demonstrated cotton suture material to incorporate the desirable qualities of pliability, satisfactory tensile strength, a high coefficient of friction, stability on exposure to heat or moisture and failure to produce tissue reaction. They undertook the comparative study of cotton, silk, linen and catgut with regard to tensile strength, tissue reaction, wound healing and bacterial contamination. Straight and knotted segments of these materials were tested before and after sterilization. Similar unreported studies were made with nylon. It was clearly demonstrated that whereas dry, unsterilized cotton has less tensile strength, size for size, than cat-

gut, silk or linen, its tensile strength is less altered by sterilization than is that of other suture materials, and after implantation in the tissues it showed much less impairment of tensile strength than did any of the others. Furthermore, when placed in tissue cotton did not cause edema or allergic responses and stimulated less cellular tissue reaction than other suture materials. Apparently its compact structure prevented ingrowth of tissue and thereby lessened the incidence of suture sinuses, common with the use of silk. It was found that sinuses were much more frequent when continuous sutures were employed than when interrupted sutures were used, probably because infections were able to traverse the entire wound along the tract formed by the continuous suture. Cotton was easily sterilized by being boiled in water for twenty minutes or autoclaved for fifteen minutes at 15 pounds (6.8 Kg.) pressure.

The preparation of cotton for clinical use will be presented more fully in a subsequent paper. However, it should be emphasized that cotton should not be sterilized on rigid spools. As previously demonstrated by Meade and Oschner, cotton contracts when heated, and if it is sterilized on a rigid spool the fibers are weakened or even ruptured, which materially decreases the tensile strength of the suture. The cotton suture should be rewound loosely on soft rubber tubing or should be rolled in small skeins of convenient size which can be placed in test tubes before sterilization.

Although we are convinced that cotton is tolerated better by tissues than silk and can be used more safely in the presence of gross contamination and infection, we are of the definite opinion that the tenets laid down by Halsted⁶ for the use of silk should apply also to the use of cotton. Halsted emphasized that: (1) only interrupted sutures should be used, (2) coarse suture material should be avoided by the use of a greater number of finer suture materials, (3) a dead space should never be bridged over as a chord subtends an arc and (4) the combined use of absorbable and nonabsorbable material should be avoided.

We have employed cotton in all types of wounds requiring interrupted sutures. Catgut has been substituted only in the infrequent instances in which a continuous suture was found expedient in an effort to conserve time, viz. in peritonealization of the gallbladder bed, in closing of the pleural flaps over the pulmonary stump after a pneumonectomy or in the mucosal suture in an intestinal anastomosis. As indicated later, we have been particularly pleased with the results obtained in contaminated and infected wounds sutured with cotton. Ordinary spool cotton (six cord), which can be bought over the dry goods counter, has proved entirely satisfactory. Sizes 80 and 50 are of suitable caliber for ligation of small vessels. Quilting cotton is used for the ligation of larger vessels and for the suture of peritoneum, fascia and skin. Occasionally it is expedient to employ heavy (no. 5, 10 or 20) mercerized crochet cotton for the ligation of large vessels, such as the pulmonary artery and veins.

The handling of nonabsorbable sutures, whether silk or cotton, is at first difficult for surgeons trained with catgut. However, the original awkwardness is usually overcome after a month's consistent use of cotton, and the results obtained well justify the effort.

CLINICAL STUDIES

Because of the convincing results obtained by Meade and Oschner in their experimental study of suture materials, cotton was adopted as the suture material

of choice by most surgeons of the Tulane University surgical service at the Charity Hospital. Since its adoption late in 1939, it has been employed in approximately 1,800 operations in this institution. In addition to its use at Charity Hospital, it has been used routinely on

Fig. 1.—Percentage of complicated wounds in relation to type of suture material employed.

private patients by a number of senior members of the staff. The results obtained have appeared satisfactory to all the surgeons using cotton, even though most of those on the Tulane staff were trained in the use of catgut and later became convinced of the efficiency of silk. Since, in the absence of definite statistical data, impressions are known to be misleading, a factual study of wound healing was initiated on Dec. 1, 1940 under the direction of Dr. Alfred B. Longacre, director of the surgical bacteriologic research laboratories of the department of surgery of Tulane University. The figures incorporated in this report are used with his permission and will be published later in more complete detail.

METHODS

A tabular form was developed on which each wound could be classified. Spaces were allowed for the patient's name and hospital number and data on the operation, the surgeon and the types of suture material. Each wound was classified postoperatively as clean, contaminated or infected. By definition a clean wound was taken to be one made under surgical sepsis and not involving the opening of the gastrointestinal tract, the biliary tract, the genitourinary tract or infected tissue. In addition the wounds made by cholecystectomy for chronic cholecystitis in which choledochostomy was not performed and by appendectomy in the absence of acute infection were classified as clean wounds. Exceptions, which were classified as contaminated, were wounds requiring skin grafting for closure, wounds in which the skin was not closed, wounds made through a previously infected area and wounds which were grossly contaminated during the operation by a break in technic. Contaminated wounds were defined further as those not classified as clean in which the operative area did not contain gross infection, such as an abscess. Infected wounds were those made in an area showing gross evidence of bacterial invasion. During the postoperative hospital stay of each patient the wound was indicated to heal by first intention or to be complicated. Complications were listed as hematoma, wound necrosis, disruption, stitch abscess, trivial infection and serious infection. These terms were defined as follows: A

hematoma is a sterile collection of whole blood, serum or plasma in or about the operative wound. Wound necrosis is necrosis of skin or subcutaneous tissues not the result of infection. Disruption is the spontaneous separation of any or all of the layers of the wound. A stitch abscess is any inflammatory or suppurative process about a skin suture or clip from which organisms can be cultured. A trivial infection is one which does not necessitate an increase in the expected length of hospitalization and which does not necessarily interfere with wound healing; a serious infection is one which interferes with wound healing or prolongs the period of hospitalization. An attempt was made to perform bacterial studies in every instance in which an infectious process was suspected; specimens for aerobic and anaerobic culture were collected from discharging wounds or by aspiration of collections of fluid. In addition the chart allowed space for information concerning the time of the first dressing, the time a complication was first noted and the condition of the wound on discharge of the patient. The data were collected through the collaboration of two members of the Tulane visiting staff and the four assistant resident surgeons who were in direct charge of the Tulane surgical wards.

RESULTS OF STUDY

From Dec. 1, 1940 to May 1, 1941, 729 operations were performed at Charity Hospital by thirty members of the Tulane surgical staff. Nine of the seventeen members of the visiting staff and all the thirteen residents and interns used cotton sutures routinely. Three visiting surgeons employed silk sutures routinely; five continued to use catgut sutures. Of 465 cases in which operative procedures were performed and cotton sutures were used the wound in 358 could be classified as clean, in 89 as contaminated and in 18 as infected. Silk sutures were employed in 61 cases, in 37 of which the wound was clean, in 21 contaminated and in 3 infected. Catgut sutures were used in 86 cases; the wound was clean in 57, contaminated in 25 and infected

Fig. 2.—Percentage of infected wounds in relation to type of suture material employed.

in 4. Silkworm gut was the sole suture material in 10 instances, and no suture was required in 107 operations.

Of the 57 clean wounds on which catgut sutures were used (figs. 1 and 2), 80.7 per cent healed by first intention, while 19.3 per cent were complicated, 14 per cent by infection. All the contaminated and infected

wounds were complicated. (Twenty-three of the 25 contaminated wounds involved operations in the region of the anal orifice.)

The results with silk were much better. Of the 37 clean wounds sutured with silk, only 5.4 per cent were complicated, 2.7 per cent by infection. However, 70.6

Fig. 3.—Appearance of a patient nine and a half months after subtotal thyroidectomy had been performed. The wound was closed without drainage.

per cent of the contaminated wounds were complicated, 67.9 per cent by infection; all the infected wounds were complicated.

Cotton sutures were employed on 351 clean wounds; of these 4.8 per cent became complicated, 4 per cent by infection (fig. 2). An observation of importance in the evaluation of wounds sutured with cotton was that almost half the contaminated wounds, or 47.6 per cent of 84, healed by first intention. This observation confirms our impression that cotton is better adapted for use in a contaminated or infected field than is any other suture material. As Meade and Ochsner¹⁰ have emphasized, cotton causes a minimal amount of edema and cellular tissue reaction, and use of it leads to a "dry type of healing" not encouraging to the development of infection.

A further consideration of the complications occurring in the clean wounds sutured with cotton will be of interest in that it may demonstrate that there are in every large series of cases certain instances in which infection is unlikely to be avoided. Representative of these are cases in which the closing of skin under tension is followed by a certain amount of necrosis of the skin flaps and cases of amputation of the lower extremity following gangrene due to peripheral vascular disease. In 7 of 14 such cases in our series it was unlikely that infection could have been avoided.

It is gratifying to us that the incidence of complications in clean wounds should be so low in an institution whose patients are drawn from the lowest economic stratum and in which more than half of the operations are performed by the resident staff. It is our belief that this result has been attained largely through the application of an exacting operative technic, an important part of which has been the use of cotton according to Halsted's principles.

The economy with which cotton can be used for sutures has been emphasized by Foss,¹¹ who stated that the annual expense of suture material in his hospital might have been reduced from \$1,500 to \$4.20 by the routine use of cotton. While economy was not a prime objective in our adoption of cotton, nevertheless it was interesting to speculate on the saving which might be made by the practice in a large public institution such as Charity Hospital. Accordingly, a survey was made of the number of operations performed and the type and amount of suture materials used in all services for one month (summarized in the accompanying table).

Cost of Suture Materials

Material	Unit Cost	Amount Used per Operation	Cost per Operation
Cotton.....	\$0.10 per 200 yards	25 yards	\$0.0125
Silk.....	\$0.933 per 25 yards	25 yards	\$0.933
Catgut.....	\$0.1925 per tube	6 tubes	\$1.16

Suture material was employed in 647 operations performed during this period. Cotton was used by members of the Tulane surgical staff in 100 surgical procedures at an average cost of 1¼ cents for the 25 yards (22.8 meters) required in each operation. Silk was employed in 78 operations at an average cost of 93 cents for the 25 yards. An average of six tubes of catgut was used in each of 469 operations, at a cost of \$1.16 per operation. The total cost of suture materials for one month at Charity Hospital was found to be \$618.06. If this month can be taken as representative of the whole year, the cost per annum of suture materials at Charity Hospital can be estimated as \$7,416.72. Use of cotton in the same number of procedures would have cost only \$97.05.

Two pictures of typical postoperative scars are shown in order to demonstrate the type of healing which is obtained with cotton. Figure 3 shows a patient who had undergone subtotal thyroidectomy nine and one-half months previously. The wound was closed without drainage and healed uneventfully. The scar is even less discernible in real life than it is in the photograph. Figure 4 shows the abdomen of a patient thirteen days after ventral herniorrhaphy. Eight years previously there had been an abscess in the same region of the abdominal wall which had been treated surgically. Following a blow on the abdomen eight months before the present admission, a second abscess formed beneath the old scar, and a hernia appeared in the same area. At operation an abscess was found surrounding a piece of silkworm gut 4 cm. in length and lying in contact with the bladder. The abscess was excised, and, despite the presence of infection, a herniorrhaphy was performed. Sulfanil-

Fig. 4.—Appearance of a patient thirteen days after ventral herniorrhaphy in an infected field.

amide was placed in the wound. Healing was by first intention, and there have been no complications in the five months since operation.

SUMMARY

1. In a previously reported experimental study, cotton suture material has been shown to incorporate the qualities of pliability, satisfactory tensile strength, a high coefficient of friction, stability on exposure to heat and moisture and the failure to produce any great tissue reaction.

2. Cotton suture material has been used routinely in the Tulane University surgical service at Charity Hospital for eighteen months, in approximately 1,800 cases.

3. A study of 465 consecutive wounds in which cotton suture material was employed demonstrated cotton to be highly satisfactory in its clinical application.

4. The low cost of cotton, while not of primary importance, is a desirable feature.

401 West Grand River Avenue—1811 Audubon Street.

ABSTRACT OF DISCUSSION

DR. DONALD GUTHRIE, Sayre, Pa.: The important things a surgeon should expect of a suture material are, first, that it should be absolutely sterile. Second, it should have the proper tensile strength when placed in the tissues, it should produce the minimal amount of tissue reaction and by its use the need for drainage of wounds should be greatly reduced, because drainage weakens all wounds and exposes them to dangers of infection. Lastly, it should be economical to use. Since Ochsner and Gage suggested the use of cotton thread to replace silk, my associates and I have used this material and are convinced that it is a much better and a safer suture to use. We feel that the knots of cotton are more secure and that it has a better tensile strength. It produces less tissue reaction and our percentage of infections is now even lower than when we employed silk. In keeping careful track of our cases for several years and comparing the results of nonabsorbable with absorbable sutures, we find that our percentage of infection following the use of nonabsorbable sutures has been much lower than that following the use of catgut; also that our percentage of recurrence following herniorrhaphy has been greatly reduced. We have been able further to dispense with drainage in cases of radical mastectomy and in practically all of our operations for thyroidectomy. Another point of advantage in the use of cotton is that patients are not allergic to the cotton—occasionally one is to silk. We agree with the authors that cotton does not produce sinus formation in the presence of infection. In our clinic cotton is used for ligatures and sutures in all herniorrhaphies, all thyroidectomies, all radical and simple mastectomies, about one half of the clean appendectomies and in about two thirds of the clean abdominal wounds. In this way we can keep a careful check of the results of cotton and of catgut. If any surgeon will investigate this question with an open mind and compare his results after the employment of nonabsorbable sutures with those in which catgut is used, he will be convinced that there are many advantages of nonabsorbable suture material over catgut. We feel that Gage and Ochsner have made a contribution to surgical practice in suggesting the use of cotton as a nonabsorbable suture, because, after a thirteen months experience with it we believe it to be a far better suture and ligature material than silk.

DR. JOHN M. FARRIS, Ann Arbor, Mich.: I am glad to report experimental data which tend to corroborate the views of Drs. Meade and Long and Dr. Ochsner. Certain controversies have come from experimental work on suture material because of the difficulty in controlling conditions. The effect of trauma and tension and incomplete hemostasis may often be confused with the presence of a suture itself. To overcome some of these objections, a series of experiments have been

carried out. A piece of silk was placed in the anterior chamber of the rabbit's eye and allowed to remain for fourteen days. During this period it may be observed through the transparent cornea. In general, there is usually but little reaction to the silk, although silk has a tendency to untwist. It is untied at the ends and its diameter has increased twice while it was in the culture medium. A piece of silk in place four weeks showed little difference in the reaction, although it still showed a tendency to untwist. A piece of catgut in three or four days showed a tendency for the strands to undergo dissolution and the aqueous humor to become somewhat opaque. At first we thought the eyes were infected, but cultures in every instance have been negative. In about two weeks the anterior chamber looks more than ever as if it were infected. There is a large amount of exudate about the strands of catgut. The entire anterior chamber becomes completely opaque, and for practical purposes the animal is blind. There is less reaction from the cotton than from any other type of suture material. The cells in the fluid when counted are difficult to find and in a series of 8 animals about 100 cells per cubic millimeter were found, while on the catgut it varied from 2,000 to 600 leukocytes per millimeter, a striking difference in the reaction. A piece of cotton that has been in the eye for four weeks has maintained its small size and its diameter. There is less tendency for it to untwist and fray at the edge. But little reaction occurs in the eye. I have had the opportunity of observing bits of cotton and silk in the eye for a period of a year. These experiments emphasize the view that all sutures are foreign bodies and as such should be used sparingly. A foreign body in some instances on the wound will delay the process of fibroplasia. The suture causes a minimum of foreign body reaction and at that time either disappears from the wound or, if it remains, its sustained presence should not be objectionable. These experiments indicate that cotton fulfils these criteria.

DR. J. E. CANNADAY, Charleston, W. Va.: I am able to corroborate what the authors and the discussers have said with regard to the use of cotton thread sutures in surgery. My associates and I have used cotton thread sutures since the first report made on the subject by Dr. Alton Ochsner in *THE JOURNAL*. Since that time we have used cotton thread sutures in between 500 and 1,000 cases, and we have recently had occasion to check over about 400 of these cases carefully and we found an incidence of infection in clean cases of about 2 per cent. We have used cotton thread sutures for almost every type of surgery and gynecology, in hernias and perineorrhaphies, in gastric and large bowel resections, cholecystojejunostomies and so on, and find that the material is thoroughly satisfactory when used in accordance with the tenets Halsted laid down for silk. We find that cotton thread suture of the finer type, say 50, is a very satisfactory suture for holding fat together. In the fat abdomen we use it. It holds and heals in beautifully. Since we have been using cotton thread sutures routinely we have had one abdominal wound disruption. That was in a resection of the stomach in which chronic bronchitis developed. However, the wound was promptly repaired with cotton thread sutures and satisfactory healing occurred without infection.

DR. ALTON OCHSNER, New Orleans: A word about the preparation of cotton: As Drs. Meade and Long mentioned, cotton contracts when heated and for this reason it should not be sterilized on a rigid spool. Sterilization can be done in one or two ways. When cotton is sterilized on a rubber tube the cotton becomes shortened and the tube compressed. Another way in which it can be done is to wrap cotton around board. This is the technic used in one of the institutions in which I work. Two ties close together are placed around the skein, and the skein is cut between the two ties. It is then placed in a test tube and autoclaved. A word about its use in cases of infection: If I should be told that I could use cotton in only one type of case, I would choose a patient who has a grossly contaminated abdominal wound. It is imperative that interrupted sutures be used. The wound, even though infected, will usually heal with no difficulty and without discharge of the cotton sutures. The incidence of infection is much less in grossly contaminated wounds than when catgut or even silk is used.

SENILE OSTEOPOROSIS OF THE SPINAL COLUMN

JOHN R. BLACK, M.D.

RALPH K. GHORMLEY, M.D.

AND

JOHN D. CAMP, M.D.

ROCHESTER, MINN.

The syndrome of senile osteoporosis as it is understood today is different in some respects from its early description. In the early cases the diagnosis was made on the basis of the clinical findings and was confirmed at necropsy; as a consequence the diagnosis was usually made in the advanced stages and the postmortem examination showed extensive osteoporosis. Today, with improved methods for diagnosis, routine roentgenologic examination may disclose the condition even without clinical signs and symptoms.

Our report is based on a study of 208 patients, 167 women and 41 men. The average age of all when first seen at the Mayo Clinic was 62, the youngest being 45 and the oldest 87. In the cases reported in the literature, somewhat more advanced ages were represented. In 42 selected from various reports the mean age was 66. These figures indicate that senile osteoporosis is definitely associated with the older age groups.

The relation of this syndrome to the female sex is striking and has been an outstanding feature of all comments, the number of women afflicted being about four times the number of men. In general, the life expectancy of women is longer than that of men; thus more women live to the ages at which osteoporosis occurs. Furthermore, women lead a more sedentary life than men, and an atrophy of disuse has been postulated; however, osteoporosis does afflict persons who have always been extremely active. Many of the patients are widowed or single, and this fact might play a part in the development of osteoporosis on the basis of inadequate diet or conditions incidental to living alone.¹ It was found that 42.5 per cent of the women and 19.8 per cent of the men were either single or widowed.

The usual history is that a woman about 59 first notices weakness, fatigue or a dull ache in the lower part of the back. The dull ache gradually becomes worse and may be diffuse all over the back. This early stage usually lasts several years. Then, as the result of a slight jar, a fall, lifting or bending there may be a sudden snap or acute pain in the back. The pain is severe and often compels the patient to go to bed for a few days or weeks. From this time on the dull backache persists; in addition, sharp agonizing pains occur in the back on the slightest movement; turning, jarring or bending is particularly likely to cause them. The pain occurs chiefly in the lower part of the thoracic region and in the lumbar region. Frequently it is projected along the nerve roots, and so a multitude of referred pains occur. These may be in the neck and shoulders, down the arms, along the ribs, over the precordium, in the epigastrium, in both flanks and over the iliac crests, or there may be associated sciatica.

From the Section on Orthopedic Surgery (Drs. Black and Ghormley) and the Section on Roentgenology (Dr. Camp) of the Mayo Clinic.

Abridgement of thesis submitted by Dr. Black to the faculty of the Graduate School of the University of Minnesota in partial fulfillment of the requirements for the degree of Master of Science in Orthopedic Surgery.

1. Meulengracht, E., and Meyer, A. R.: Osteomalacia of the Spinal Column, *Acta med. Scandinav.* 92: 584-602, 1937.

Their relationship to the condition of the back may be noted because of the aggravation that occurs with movement. Although these pains may be strictly localized to one nerve root, it is rare to find any neurologic signs, such as changes in sensation or reflexes.

The average duration of symptoms was three years, although in several cases symptoms referable to the back had been present for twenty to fifty years. These, however, could not be ascribed to osteoporosis. The occurrence of mild trauma as the primary agent in the onset of acute symptoms has been ascribed to preexisting osteoporosis in which mild trauma has produced collapse of a vertebra and severe pain. The pains, in addition to being made worse by movement, are aggravated by lifting, coughing or sneezing, and in some cases the weather may have some effect. Relief is usually obtained in the recumbent position, although turning over in bed often causes severe pain.

Other symptoms are weakness, easy fatigue and nervousness. The patients frequently have a sensation that the back is likely to give way; this may be interpreted as weakness. Decourt² expressed the opinion that the nervousness and depression observed are part of the syndrome and that frequently they disappear and are replaced by euphoria with successful treatment of the condition. With the progress of the atrophy of bone the patients themselves notice and their friends remark that they are becoming "round shouldered" and are losing stature. The pain in the back and the root pain gradually become worse and finally compel the patient to go to bed for relief. Patients who have died have done so as a result of associated disease.

On physical examination, the patients present all the signs of senility, general atrophy of the tissues and arteriosclerosis. Frequently they are thin and emaciated, although various states of nutrition are seen. In our series the average height of the women was 5 feet 3 inches (160 cm.) and the average weight was 122½ pounds (55.6 Kg.); of the men, 5 feet 7 inches (170 cm.) and 152½ pounds (69.2 Kg.). These figures indicate that the general nutrition was fairly good in the entire group but was better among the men than among the women. The typical appearance in advanced stages is that of a thin little old woman (fig. 1 a, b, c), with loose wrinkled skin and a rounded back, who walks with short, careful steps in order to avoid jarring. The whole body is held tense in walking by protective muscle spasm. The rounded dorsal kyphosis causes the cervical segment of the spinal column to project forward; this is compensated for by an increase in the normal cervical lordosis. Movements of patients without pain or tenderness are free and normal in range; the usual picture, however, is that of marked limitation, due to muscle spasm, of motions of the spinal column. Tenderness on pressure over the spinous processes is not severe or well localized, but bending and jarring bring on severe pains. On the other hand, many patients are remarkably well preserved, well nourished and healthy in every way except for their complaints in regard to the back.

LABORATORY FINDINGS

The urine usually was normal but occasionally showed small amounts of albumin or pus. In 33 cases the blood showed 12.5 Gm. of hemoglobin or less, per hundred cubic centimeters, whereas examination of

2. Decourt, Jacques: A propos des hernies intrasponeuses multiples du disque intervertébral, *Bull. et mém. Soc. méd. d. hôp. de Paris* 50: 857-858 (June) 1934.

blood smears and other hematologic studies established a diagnosis of pernicious anemia in 3 cases and of macrocytic anemia in 4. The flocculation reaction was positive in 10 and doubtful in 3. Gastric analysis was carried out in 29 cases, and there was absence of free hydrochloric acid in 11.

A total of 92 determinations of serum calcium were carried out in 68 cases. The average value was 9.8 mg. of calcium per hundred cubic centimeters; the range was 7.8 to 12.7 mg. The great majority of readings were between 9 and 11 mg. Seventy-seven determinations of inorganic phosphorus in the serum were carried out in 58 cases. The mean value was 3.4 mg. per hundred cubic centimeters, with a variation from 2.1 to 6.5 mg. Similarly, 60 determinations of phosphatase in the serum were carried out in 47 cases. The mean value was 3.8 Bodansky units, with a range from 2 to 13.4 units. In 6 cases in which the values were abnormally high or low, no other cause was found to account for the unusual

disks. The researches of Schmorl and his co-workers on several thousand spinal columns examined at necropsy are outstanding in their demonstration of the normal anatomic and histologic characteristics of the spinal column, as well as of the changes which occur at various ages throughout life under the influences of age, normal activity, trauma and disease. The descriptions that follow have been taken mainly from the writings of Schmorl and his co-workers,³ although other authors have written on the subject.⁴

Senile osteoporosis, involving as it does primarily the trabeculae of spongy bone, is most evident in the vertebrae. Schmorl⁵ has demonstrated the changes in the vertebrae by making preparations in which the marrow tissue and other organic elements have been removed. The cortical bone is much thinner than normal, and there is enlargement of the marrow spaces and the medullary cavity. The surfaces of the trabeculae are clean and smooth and indicate a long, slow, vascular

Fig. 1—*a*, Rounded kyphosis of the thoracic segment of the spinal column resulting from senile osteoporosis; *b*, forearm of the same patient revealing moderate osteoporosis; *c*, lumbar segment of the spinal column revealing osteoporosis, expanded intervertebral disks and compressed vertebrae.

values and subsequent determinations gave normal values. In 1 case in which there was an elevated concentration of serum calcium exploration of the parathyroid glands did not reveal a tumor or hyperplasia. In 2 cases of extensive osteoporosis with chemically normal blood constituents exploration was made, and in both cases the parathyroid glands were found to be normal, in agreement with the reports on similar cases by other authors.

The sedimentation rate of the erythrocytes was determined in 31 cases; the average rate was 22 mm. in one hour, with a range from 3 to 58 mm. In some of the cases in which an increased sedimentation rate was noted there was an associated infection; in the others, however, no adequate explanation could be found for the increased rate, although it was not felt to be due to the osteoporosis.

GROSS PATHOLOGIC CHANGES

The changes which occur in the spinal column depend on the degree of atrophy of bone and on the anatomic peculiarities of the vertebrae and the intervertebral

resorption rather than an osteoclastic resorption, in which the surfaces would be rough and irregular. The individual trabeculae are much thinner and fewer than is normal, but their architectural arrangement is maintained.

When osteoporosis has progressed to a certain degree, the bony trabeculae are no longer able to resist the weight of the body and the internal pressure of the intervertebral disks. There occur a collapse of the central portions of the vertebral body and expansion of the nucleus pulposus and disk. The appearance of the narrowed vertebrae has been likened to that of "fish vertebrae" by Schmorl.⁶ This mechanism will not

6 Schmorl, G.: Die pathologische Anatomie der Wirbelsäule, *Verhandl. d. deutsch. orthop. Gesellsch.* 21:3-39, 1926.

occur if the disks, through degenerative processes, have lost their expansibility. Fissures and cracks in the cartilaginous plates, arising through repeated small injuries incidental to normal activity, may allow the tissue of the nucleus pulposus to work its way out into the substantia spongiosa, giving rise to Schmorl's nodes. The vertebral bodies may collapse in their anterior part, as in a true compression fracture; in this way numerous pathologic fractures occur, either without any or with only minor degrees of trauma.

Degenerative changes in the disks occur usually in the upper thoracic region and lead to thinning of the disks, hypertrophic changes about the anterior margins of the vertebral bodies and dorsal kyphosis. This type of kyphosis is the usual one seen in old persons. The disks in the lower thoracic region and in the lumbar region

Fig 2.—Extreme osteoporosis of thoracic and lumbar vertebrae with compression fractures and expanded intervertebral disks. This patient was obese.

maintain their expansibility longer than those in the upper thoracic region. They are also normally more expansile, and so the phenomenon of ballooned disks is more often seen in the lower thoracic and the upper lumbar region.

ROENTGENOLOGICALLY APPARENT CHANGES IN SENILE OSTEOPOROSIS

The distribution of the ballooned disks and compressed vertebral bodies in our group was the same as that found by Junghanns.⁷ The intervertebral disks in the lower thoracic and the lumbar region were the ones most frequently involved, and the vertebrae in the same regions were most frequently compressed. In general, the degree of expansion and the number of vertebrae

compressed depend on the grade of osteoporosis. In some patients, all the disks in the thoracic and lumbar regions were ballooned (figs. 2 and 3) and many vertebrae were crushed. In others few such changes were present. Of 18 patients with osteoporosis grade 1 (on a basis of 1 to 4), none had ballooning of the disks; of 47 with osteoporosis grade 2, 34 per cent had ballooning; of 45 with osteoporosis grade 3, 93.3 per cent had ballooning, and of 19 with osteoporosis grade 4, all had extensive ballooning. The incidence of compression of the vertebrae showed a similar variation with the degree of osteoporosis, whereas the presence of hypertrophic changes was common to all groups and showed little relationship to the degree of atrophy of bone.

The cause of the backache and of the sharp radiating pains in osteoporosis has always been a source of discussion. The dull backache has been attributed to osteoporosis per se, and the attribution appears to be justified in many cases because of the association of this type of backache with mild osteoporosis. However, many patients have severe osteoporosis without pain. The sharp pains occur definitely along nerve roots, but they are not due to pressure on the roots, because the foramina are usually free. These pains bear a definite relationship to the site of the ballooned disks and compressed vertebral bodies. The most satisfactory explanation is that the pain is a reflex one that arises from the recently compressed vertebrae and is referred along the nearby nerve roots. Many ballooned disks and compressed vertebrae may be present without related pain.

It has been our impression that in the syndrome of senile osteoporosis of the spinal column, the osteoporosis attains its greatest degree in the bones of the vertebral column. This impression is borne out by the roentgenologic findings in 23 cases in which roentgenograms of the long bones of the upper or the lower extremity, in addition to those of the vertebral column, were available for study.

DIFFERENTIAL DIAGNOSIS

The numerous factors and diseases which lead to atrophy of bone in the spinal column of adults frequently occur in persons in the older age groups and so must be distinguished from senile osteoporosis.

Hyperparathyroidism.—Senile osteoporosis has probably been erroneously diagnosed as hyperparathyroidism more often than as any other condition, and even today an unequivocal roentgenologic diagnosis of senile osteoporosis is difficult to make without first ruling out hyperparathyroidism. The fact that the results of laboratory tests, usually relied on to distinguish between the two, may be within normal limits makes the problem in some cases even more difficult.

Hyperparathyroidism produces a generalized osteoporosis described by Bauer and Camp,⁸ by Camp⁹ and by Camp and Ochsner¹⁰ as a peculiar, miliary mottling and granular appearance of the bone best seen in the flat bones. The roentgenograms of the spinal column may closely resemble those characteristic of senile

osteoporosis, but the characteristic osteoporosis in the skull and flat bones and the subperiosteal decalcification, bowing, fractures and cyst formation in the long bones, in most cases, are easily distinguished from the homogeneous osteoporosis in the flat bones and the slight changes in the long bones seen in cases of senile osteoporosis. When roentgenograms do not give conclusive evidence of hyperparathyroidism, the results of laboratory tests frequently will confirm the diagnosis. The concentration of serum calcium is usually 11 mg. or more per hundred cubic centimeters, and the concentration of inorganic phosphorus in the serum is lowered, whereas the value for serum phosphatase is usually high. The final test is a marked increase in the urinary excretion of calcium and phosphorus. These values are all within normal limits in senile osteoporosis.

Hyperthyroidism.—Roentgenologically, the changes in the spine in some cases of exophthalmic goiter are indistinguishable from those of senile osteoporosis.¹¹ If the patient is less than 40, the question of senile osteoporosis does not arise; with older patients, the diagnosis is made on the basis of the clinical history and findings of exophthalmic goiter. The blood chemistry is normal, the basal metabolic rate is increased and the excretion of calcium is markedly increased, according to studies of the calcium balance. The degree of osteoporosis depends on the length of time that hyperthyroidism has been present and may be out of all proportion to the increase in the basal metabolic rate.¹²

Pituitary Basophilism and Adrenocortical Syndromes.—The syndrome of pituitary basophilism and the adrenocortical syndrome both include a homogeneous, generalized atrophy of bone practically identical with that found in senile osteoporosis.¹³ The age of some patients and the physical characteristics of obesity, hypertension, hirsutism and abdominal striae with changes in the primary and secondary sex characteristics serve to distinguish these conditions from senile osteoporosis. However, there were a number of cases in the group studied in which osteoporosis, hypertension and obesity occurred; the other characteristics of these two syndromes were not noted. Similar observations by others have led to the hypothesis that senile osteoporosis is due to changes in the pituitary gland and in other glands of internal secretion.¹⁴

Metastatic Malignant Lesions.—The question of the presence of an osteoclastic type of metastatic malignant lesion frequently arises in connection with extensive osteoporosis of the spinal column of persons more than 40. The diagnosis is usually made without difficulty, roentgenologically, by the presence in malignant disease of localized regions of destruction, invasion of the pedicles of the vertebrae or regions of destruction in the flat bones. However, the osteoporosis caused by infiltration of malignant tumor cells is often homogeneous in its distribution. The softened vertebral bodies under the effect of the expansile intervertebral disks

become "fish vertebrae," and many pathologic fractures occur.¹⁵ Two factors of great value in the diagnosis of generalized carcinomatosis with or without a known primary lesion are the sedimentation rate and the blood smear. The sedimentation rate of the erythrocytes is rapid and, in the absence of infection or other factors causing such a high rate, is diagnostic of generalized carcinomatosis. The blood smear in cases in which there is extensive metastasis to bone frequently shows immaturity of the myeloid cells, the so-called leukemoid reaction, and in the absence of other factors causing such a change is also diagnostic of metastasis of a malignant tumor to the bone marrow.

Multiple Myeloma.—Multiple myeloma, like metastatic carcinoma and by the same mechanism, may give rise in the vertebral column to osteoporosis, ballooned

Fig. 3—Senile osteoporosis of the lumbar segment of the spinal column with expanded intervertebral disks and compressed vertebrae.

intervertebral disks and collapsed vertebrae identical with the roentgenographic picture of senile osteoporosis. Usually, however, localized evidence of destruction of bone is seen in the ribs, the pelvis and most clearly of all in the skull.⁸ The clinical symptoms are similar to those of senile osteoporosis except that the pain is more severe. It persists even while the patient is recumbent and may require morphine for relief. Secondary renal changes are common and may lead to albuminuria and an increase in the nonprotein nitrogen of the blood.¹⁶ Bence-Jones protein in the urine in some cases of multiple myeloma clearly distinguishes the condition from senile osteoporosis, in which Bence-Jones proteinuria is absent. Sternal puncture will reveal the presence of myeloma cells in a high percentage of cases.

16. Geschickter, C. F., and Copeland, M. M.: Tumors of the Bone (Including the Jaws and Joints), revised ed., New York, American Journal of Cancer, 1936, pp. 441-488.

Chronic Infectious Arthritis.—Extensive osteoporosis is frequently seen in the spinal column and around the involved joints in cases of chronic infectious arthritis. It is difficult to say whether this atrophy of the bone is produced by the infectious process itself or whether it is the result of the disuse and inactivity so commonly an accompaniment of this disease. In excluding cases of chronic infectious arthritis from the group of cases of senile osteoporosis, certain criteria were used. The history of a prolonged course of pains, stiffness, redness and swelling of other joints, particularly if the disease came on before the age of 40, with anemia, an increased sedimentation rate, atrophy and destructive changes in other joints, was taken as sufficient evidence of chronic infectious arthritis.

Spondylitis Deformans.—In cases of early spondylitis deformans there is mild to moderate osteoporosis without the extensive ankylosis of all the vertebrae that is so evident in the late stages of the disease. This condition usually occurs in younger persons; they complain of stiffness and pain in the back which persists on lying down and is worse in cold damp weather. Examination reveals much limitation of motion in the spinal column and in expansion of the thorax. Roentgenographically, destructive changes in the sacroiliac joints and intervertebral facets, with beginning calcification of the spinal ligaments, indicate the presence of spondylitis deformans. Examination of the blood frequently reveals evidence of secondary anemia and an increased sedimentation rate. In senile osteoporosis there is not the destruction of these joints or the calcification of ligaments that is seen in spondylitis deformans, nor is there an increased sedimentation rate.

Osteomalacia.—It is now known that the essential factor in the production of osteomalacia is a failure of the intake¹⁷ of calcium, phosphorus and vitamin D to satisfy the bodily requirements for these substances. It is the adult equivalent of the rickets of children. Osteomalacia associated with pregnancy and lactation is rarely seen in most countries, but it is still endemic in China and certain parts of India. Osteomalacia may occur with various nutritional deficiencies, such as idiopathic steatorrhea, sprue,¹⁸ celiac disease and other conditions.¹⁹ The concentration of calcium in the blood is high, as in rickets.

Roentgenologically the changes in the spinal column may be the same in both osteomalacia and senile osteoporosis, but usually there is marked distortion of the bony pelvis, and the long bones are involved to a greater extent in osteomalacia than is ordinary in senile osteoporosis. In addition osteomalacia is characterized by symmetrical areas of decalcification or pseudofractures of the long bones, the so-called Looser zones. It may be impossible to distinguish mild osteomalacia from senile osteoporosis unless the age of the patient is such as to exclude the latter.

ETIOLOGY

It has been generally accepted in the past that osteoporosis is a natural accompaniment of advancing age. However, when one observes a large number of elderly persons, it is readily apparent that only a small proportion suffer from a severe lack of calcium in their bones. One is therefore led to believe that senile osteoporosis is a pathologic process. Many hypotheses have been proposed to explain its onset, the more important of which may be listed as follows: dietary deficiency, gastric achlorhydria, endocrine imbalance and inactivity.

It is certain that in not all cases of osteoporosis is there deficiency in the calcium intake, and so other hypotheses have been put forward. The place that gastric acidity plays in the absorption of calcium has been stressed recently. It is reasonable to suppose that achlorhydria when present may play a part in the production of osteoporosis by interfering with the absorption of calcium. However, it can be only a minor part, for Schmidt and Greenberg²⁰ have shown that normal assimilation of calcium does occur in the absence of hydrochloric acid in the stomach. In the present study, gastric analysis was carried out in 29 cases. In 18 the contents of the stomach showed normal values for hydrochloric acid, and in 11 free hydrochloric acid was absent. These results would indicate that achlorhydria may be a factor in the production of osteoporosis in some cases but that in the majority of cases other factors are responsible.

It has been pointed out that in pituitary basophilism²¹ there is extensive osteoporosis. Rutishauser and Maubetsch²² in 1934 proposed the hypothesis that in old age there is a proliferation of the basophilic cells and therefore a relative preponderance of these cells in the pituitary gland and that the secretion derived from them causes osteoporosis. There has been little confirmatory evidence for the theory. There have been various attempts to show that senile osteoporosis is the result of parathyroid hyperplasia. However, these probably involved errors in diagnosis, since the preponderance of evidence seems to indicate that in senile osteoporosis the parathyroid glands are normal. In the present series, the parathyroid glands were explored in 3 cases and in all 3 were entirely normal.

Associated with the osteoporosis in our cases were a group of diseases, many of which, for example, arteriosclerosis, coronary sclerosis and cardiac failure, were associated with old age and had no bearing on the occurrence of atrophy of bone. Others, such as hypertension, cholecystitis and asthma, were regarded as incidental. There was a small group of diseases which did perhaps play some secondary part in the production of osteoporosis. In 3 cases of pernicious anemia, malnutrition and achlorhydria may have affected the absorption of calcium. In 8 cases of diabetes mellitus, acidosis or dietary regulation may have interfered with the calcium metabolism. Golden and Abbott²³ and others have noted the association of diabetes mellitus with osteoporosis. In 1 case of duodenal ulcer and in 1 of Addison's disease, the diet and malnutrition may have played parts in the causation of the osteoporosis.

In 33 cases there was moderate secondary anemia. The anemia is suggestive of general poor health which might have been an etiologic factor in the osteoporosis.

TREATMENT

The object of therapy in cases of senile osteoporosis is threefold: first, to relieve the severe pain; second, to prevent further deformity, and third, to promote

TABLE 1.—Results of Treatment in Senile Osteoporosis

Type of Treatment	Result							
	Group 1*		Group 2		Group 3		Group 4

Total.....	13	81.1	23	31.9	29	40.3	7	9.7

* Group 1 "cured" or "very much better"; group 2 "much better" or "better"; group 3 "the same" or "a little better"; group 4 "worse."

recalcification of bone. Relief of pain is best obtained when the patient is recumbent. Too prolonged rest in bed should be avoided, since inactivity tends to cause increased atrophy of bone and it is difficult to get patients up and about again. In addition, the application of heat and massage to the spine does much to relieve pain and muscle spasm.

The problem of preventing further loss of calcium from the bones is one of diet and nutrition. The first consideration in the diet is that the carbohydrate, fat and protein constituents be adequate, for many old persons are undernourished and anemic, and their dietary habits are often faulty. Good general health aids in the normal absorption and utilization of calcium,²⁴ phosphorus and vitamin D. The diet should include milk, cheese, eggs and other foods high in calcium and phosphorus in order to supply these elements in the forms in which they are most easily absorbed.²⁵

In practice, the diet is supplemented by salts of calcium and phosphorus and concentrates of vitamin D. Calcium salts may be given orally, intravenously or intramuscularly. Calcium is utilized better when parenterally administered than when taken orally; however, parenteral administration is disagreeable to the patient and is impractical, especially when treatment extends over months and years, because the end results are the same as for oral administration. Different authors have used various salts, such as calcium chloride, calcium lactate, calcium gluconate, calcium chlorate and calcium glycerophosphate, with equally favorable results for various conditions requiring calcium therapy. In order to supply both calcium and phosphorus, various phos-

phate salts of calcium have been used.²⁶ These are relatively insoluble, but in the presence of adequate amounts of vitamin D they are readily absorbed.²⁷ Tri-basic calcium phosphate has been most commonly used at the Mayo Clinic because it contains more calcium and phosphorus per gram than the other salts. Although the daily requirement of calcium is about 0.5 to 1 Gm. in actual treatment an excess is given to insure adequate absorption.²⁸ The dose for tribasic calcium phosphate is 1 teaspoon three times a day. It has been pointed out that vitamin D is essential for the absorption and utilization of calcium and phosphorus. The daily dose recommended is 625 units²⁸ for normal adults; 10,000 to 50,000 units may be used in the treatment of vitamin D deficiency states.

The consensus in regard to the efficacy of treatment of senile osteoporosis seems to be one of confirmed pessimism; however, most reports have shown favorable progress of patients treated with calcium and vitamin D. The results of treatment in our group have been studied to determine how beneficial the therapy was. Many patients could not be traced, others had died and for those who did reply it was sometimes difficult to evaluate the effects of the separate therapeutic procedures advised. Follow-up reports were received on 83 cases, in 11 of which death had occurred and there was no information available relating to the condition of the spinal column. In the remaining 72 the average time elapsed since the initial examination and treatment was two and three-tenths years; the longest time was nine years. In order to compare the effect of the various therapeutic measures (table 1) the patients were divided into four groups: (1) "cured" or "very much better," (2) "much better" or "better," (3) "the same" or "a little better" and (4) "worse." The symptoms of 50 per cent of the 72 patients were definitely improved. When we compare the patients treated with calcium and phosphorus, with vitamin D or with all three drugs with those who did not receive these essentials we find that 54 per cent of the former and only 33 per cent of the latter were benefited by the treatment.

TABLE 2.—Relation of Duration of Treatment to Results for Patients to Whom Calcium, Phosphorus and Vitamin D Were Given

Duration of Treatment	Result				Total
	Group 1*	Group 2	Group 3	Group 4	
Six months and less.....	1	2	2	2	7
Six months to a year.....	4	5	3	0	12
One to two years.....	1	4	3	0	8
More than two years.....	4	5	3	1	13
Unknown.....	5	..	5
Total.....	10	16	16	3	45

* Group 1 "cured" or "very much better"; group 2, "much better" or "better"; group 3 "the same" or "a little better"; group 4 "worse."

When results are considered with respect to the length of time the treatment was carried out (table 2), only the group of cases in which calcium, phosphorus and vitamin D were given can be studied. In the other groups, there were many cases in which the length of time that the treatment had been given could not be

determined, and the remaining cases were too few for comparison. The symptoms of only 43 per cent of the patients treated for less than six months were improved. On the other hand, the symptoms of 70 per cent of the patients treated for six months or longer were improved.

With regard to the roentgenographic evidence of improvement, there were 18 cases in which follow-up roentgenograms were available. The roentgenograms were taken on an average of twenty-nine months after the beginning of treatment. In no case was there a sufficient change to enable one to say that it was due to recalcification and not to variation in the technic used in taking the roentgenogram.

CHANCROID

TREATMENT WITH SULFATHIAZOLE AND SULFANILAMIDE

BORRIS A. KORNBLITH, M.D.

ADOLPH JACOBY, M.D.

AND

LOUIS CHARGIN, M.D.

NEW YORK

This report deals with 175 patients with chancroid, 150 treated with sulfanilamide and 25 with sulfathiazole. There were 167 men and 8 women, 127 Negroes, 44 white persons, 3 Puerto Ricans and 1 Chinese. The average age was 30.2 years, the youngest patient being 18 and the oldest 58. The majority of the lesions were on the external genitalia (fig. 1). Two patients had ulcerations on the pubis, and 2 had them around the anus. Forty-eight had multiple lesions. The average duration of the lesions was thirty-one days. There were two of five days' and one of three years' duration.

DIAGNOSIS

The diagnosis of uncomplicated chancroid was based on the identification of *Hemophilus ducreyi* on smear from a characteristic ulcerative lesion and a positive reaction to Ducrey vaccine given intradermally. In addition, absence of *Treponema pallidum* on dark field examination and negative Wassermann and Frei reactions were required.

The most reliable single factor in the precise diagnosis of chancroid is the identification of the Ducrey bacillus, discovered by Augusto Ducrey of Rome in 1892 (fig. 2). The failure to demonstrate Ducrey bacilli on smear does not necessarily rule out this disease. Lesions which are contaminated or treated with caustics, or of long duration, with sloughing areas, or multiple infections often yield poor smears in which it is difficult to identify the organism. After thorough cleansing of such lesions with saline solution for two days repetition of the smear is more likely to reveal it. Among the 175 cases reported here the Ducrey organism, stained by the Unna-Pappenheim method, was demonstrable in 155 (88.5 per cent) and not found in 20 (11.5 per cent). In the 20 cases the reaction to the intradermal injection of Ducrey vaccine was positive.

REACTION TO INTRADERMAL INJECTION OF DUCREY VACCINE

The reaction following the intradermal injection of 0.1 cc. of Ducrey vaccine is specific.¹ At the end of

forty-eight hours, a papule 10 mm. in diameter, surrounded by a zone of erythema 5 mm. wide, denotes a positive reaction. A negative reaction leaves little to be seen at the site of inoculation (fig. 3). The test was introduced by Ito in 1913 and later by Reenstierna. In 1923 Nicolle and Durand in France introduced a commercial product known as dmelcos vaccine. Both these vaccines employ killed Ducrey organisms. A suitable tested domestic vaccine is now available commercially. The reaction becomes positive for the first time between eight and fifteen days after the appearance of the local lesion.² A negative reaction after this time rules out a chancroidal infection in about 95 per cent of cases.³ A positive reaction may mean that the patient has a chancroidal lesion at the time the test is performed or that he has had a chancroidal lesion at one time. The reaction probably remains positive throughout the patient's life. We have observed no reversal of the intradermal reaction after successful therapy.

Table 1 indicates that in cases of proved chancroid there were only 5.4 per cent of negative reactions. In the cases of other diseases listed, in which there was no clinical evidence of or smear positive for chancroid, the large number of positive reactions to intradermal injections of vaccine likely indicates past chancroidal infections.⁴

CLINICAL CHARACTERISTICS

In all cases there were definite ulcerations suggestive of chancroid. Inguinal adenitis was present in 73 (42 per cent); in 55 (75 per cent) it subsided without suppuration, and in 18 (25 per cent) the abscess broke down. In 8 of the 18 cases of definite inguinal abscess there was draining of the inguinal sinuses due to spontaneous rupture of the abscesses. There were 55 cases (75 per cent) of unilateral and 18 (25 per cent) of bilateral adenopathy.

The chancroidal bubo consists of inguinal nodes which are acutely inflamed and matted together and are extremely tender. The bubo is associated with systemic manifestations, such as fever, malaise and leukocytosis. The purulent material aspirated from broken down abscesses is thick and has a characteristic brick red color. In many cases the pus aspirated will not show organisms on smear or culture, although a potent antigen

Fig. 1.—Chancroidal ulceration of the prepuce throughout the entire circumference, with the consequent production of paraphimosis.

for the Ducrey intradermal test may be prepared in a manner similar to that used for the Frei antigen. In some cases, however, Ducrey bacilli may be cultured from the inguinal abscess.⁵

METHOD OF TREATMENT AND RESULTS

The earliest reports of successful therapy of chancroid with sulfanilamide appeared in the United States and in England almost simultaneously in March,⁶ April⁷ and May⁸ 1938. Since then confirmatory reports have come from many sources here and abroad.⁹

Fig. 2.—Ducrey organisms. Note the parallel “school of fish-like” arrangement of the organisms as they are seen on direct smear from chancroidal lesions.

All our patients were ambulatory and were seen in a clinic. Of the 175 treated, 150 received sulfanilamide orally, 1.2 Gm. (20 grains) four times a day for the first five days, followed by 0.6 Gm. (10 grains) four times a day for the next nine days, a total of 45.6 Gm.

TABLE 1.—An Evaluation of the Intradermal Reaction to Ducrey Vaccine*

Clinical Diagnosis	Number of Cases	Positive Reactions		Negative Reactions	
		Number	Percentage	Number	Percentage
Chancroid					
With adenitis.....	33	33	94.6	0	5.4

* The Ducrey vaccine was supplied by the Lederle Laboratories, Inc.

(700 grains) in fourteen days.¹⁰ The remaining 25 patients received sulfathiazole orally, 0.5 Gm. (7.5 grains) four times a day for ten days. Thus a total of 20 Gm. (300 grains) was used.¹¹ At the end of the stated period administration of each drug was stopped whether or not the lesion had healed.

Mild toxic phenomena, such as occasional nausea, dizziness and cyanosis, were present in the sulfanil-

amide-treated group. Two patients in the sulfathiazole group had conjunctivitis and 1 erythema nodosum during therapy. The two groups were singularly free of any major toxic reactions. There was no anuria or hematuria.

Local application of powdered sulfanilamide or sulfathiazole proved efficacious for superficial lesions.¹² For deeper ulcerations of long duration oral therapy was needed in addition to produce healing.¹³ There is no contraindication to the simultaneous use of local and systemic chemotherapy. The results of therapy were uniformly successful with the two drugs. All lesions healed within an average of fourteen days. In this series we did not find any lesions resistant to the form of therapy employed (figs. 4, 5 and 6).

SURGICAL ASPECTS OF CHANCROID

Before the advent of chemotherapy surgical intervention in cases of chancroid included incision and drainage of fluctuant buboes, the “dorsal slit” of the prepuce, cauterization of open lesions and circumcision. Since the introduction of sulfanilamide and its derivatives, radical elective surgical procedures have been eliminated. In all the cases of inguinal adenopathy, with or without abscess formation, there was no necessity for incision. Aspiration was found sufficient when necessary. As a general rule, any incision of the prepuce in the presence of an active chancroidal lesion will result in the implantation of the Ducrey organism in the incision. Thus a spread of the local infection by unavoidable autoinoculation is produced and defeats the purpose for which the incision was originally performed.

In a series of 247 cases of circumcision for chancroid reported from Cleveland,¹⁴ “autoinoculation along the line of incision was almost invariably encountered but was not troublesome when local treatment was instituted with various antiseptic solutions over a period of twenty-eight days in a hospital.” Circumcision of a patient who has active chancroidal disease on the

Fig. 3.—Intradermal reaction to Ducrey vaccine forty-eight hours after the test was performed. Note the vesiculation of the central nodule and the peripheral erythema.

genitals, even with paraphimosis, has not been found advisable or necessary in any of the cases here reported. The edema and infection subsided with oral chemotherapy.

Circumcision after cure of a chancroidal infection should be deferred for at least two or three months after all signs of local infection have completely subsided. The risk of poor healing or reactivation of sluggish organisms in the depths of the tissues if operation is performed earlier is always present.

Fig. 4.—Multiple chancroidal ulcerations in the pubic region; duration four weeks.

Biopsy of genital lesions for diagnosis has been advocated.¹⁵ The histologic differentiation of chancroid from lesions which may simulate it, i. e., lymphogranuloma venereum, granuloma inguinale and syphilis, is difficult. The lesions are all granulomas and depend on the isolation of the individual causative organism for their specific identification. We find that biopsies are essential and of value when bacteriologic methods have failed or when a lesion fails to respond to specific therapy. Whenever the possibility of carcinoma arises biopsy is definitely indicated. In one year, 2 squamous cell carcinomas, 1 of the penis and 1 of the anus, and 2 adenocarcinomas of the rectum were discovered by biopsy. Indiscriminate biopsies, however, are not advisable.

REINFECTION OR RELAPSE

Among 50 patients whose course was followed for two months to three years, 6 had subsequent ulcerations in which Ducrey bacilli were demonstrated. The intervals between the appearance of the successive lesions were in case 1 three weeks, in case 2 seven months, in case 3 four months, in case 4 two and one-half months, in case 5 ten months and in case 6 two years. The subsequent lesions occurred at a site different from the original one in all but case 2. A brief description of cases 1 and 2 follows:

CASE 1—A Negro youth aged 20, first seen April 29, 1938, was treated successfully with sulfanilamide for two chancroidal lesions on the corona penis. The lesions healed completely in ten days. He returned three weeks later, with a fresh ulceration on the frenulum, admitting unprotected coitus in the interval. This lesion, which showed Ducrey bacilli, likewise healed promptly when sulfanilamide was given orally. The patient has remained well for twenty months.

CASE 2—A Negro aged 30, first seen March 17, 1939, was successfully treated with sulfanilamide for four ulcerations on the prepuce and bilateral inguinal adenitis of two weeks' duration. The lesions healed in fourteen days. On Oct. 2, 1939, seven months after the original lesions had healed, he

returned with a fresh group of five ulcerations on the prepuce, with bilateral suppurative inguinal adenitis of three weeks' duration. The new lesions responded to oral sulfanilamide therapy, which produced healing in sixteen days. The inguinal abscess was absorbed.

In all 6 cases a definite history of repeated unprotected coitus was obtained. In case 1, in which the interval between the appearance of fresh lesions was only three weeks, the possibility of relapse must be considered. The lesion, however, was at a new site, and since it healed the patient has had no further recurrence. In every case the subsequent lesions responded to a second course of therapy and have remained healed. The weight of evidence would seem to indi-

cate that reinfection rather than relapse occurred in all the cases mentioned. There were, however, 2 cases of definite relapse in which sulfathiazole powder applied locally had been used alone and in which the response to oral medication with sulfathiazole was prompt.

Fig. 5.—The same lesion as in figure 4, five days after sulfanilamide therapy.

ASSOCIATED LESIONS

The presence of more than one venereal disease is not the exception but rather a frequent occurrence. Among 175 patients less than half (46 per cent) appeared with one disease; the remaining 54 per cent had two, three or four venereal infections simultaneously or in quick succession. Among the patients with chancroid associated with syphilis 3 had a primary

15. Fund, E. R.; Greenblatt, R. B., and Hull, G. B.: Histologic Differentiation of Venereal Granuloma, Lymphogranuloma and Chancroid, *Am. J. Syph., Gonorr. & Ven. Dis.* 22: 495, 1938.

syphilitic chancre. The association is uncommon because of the difference in the incubation periods of the two diseases. A brief description of 3 cases follows:

CASE 1.—A Negro aged 22 had two ulcerations on the prepuce which had not healed for two months. He was found to have two separate ulcerations, one on the frenulum and another on the dorsum of the glans penis. The Wassermann test, dark field examination and Frei test all gave negative results. Sulfanilamide was given orally, and the ulceration on the frenulum healed over within five days. The lesion on the dorsum of the glans penis, however, became more indurated. Another dark field examination revealed *T. pallidum*.

CASE 2.—A Negro aged 39 was seen on Jan. 19, 1938, with a definite syphilitic chancre; dark field examination gave positive results. He was given six injections of neoarsphenamine, and the chancre healed over within two weeks. However, three more ulcerations on the corona penis, which were also present, began to get larger. These proved to be chancroidal ulcers, which healed promptly with sulfanilamide therapy.

Fig. 6.—The same lesion as in figure 4; there is complete healing fourteen days after sulfanilamide therapy.

CASE 3.—A white man aged 25 was admitted with two dime-sized ulcerations on the frenulum and corona penis of one week's duration. The Wassermann reaction was negative; dark field examination gave negative results; smears for Ducrey organisms were positive. Both ulcerations healed promptly with sulfanilamide therapy in fourteen days. The patient returned two weeks after healing took place with a fresh ulceration on the frenulum, the site of one of his previous ulcerations. Dark field examination of this lesion revealed *T. pallidum*. It is most likely that a simultaneous infection took place in this case, since the chancroid appeared within one week and the syphilitic chancre two weeks after the chancroid had healed.

These 3 cases illustrate that while sulfanilamide and its derivatives have no effect on syphilitic lesions, anti-syphilitic therapy has no beneficial effect on concomitant chancroidal lesions.

In the treatment of the patient with multiple infections, the simultaneous administration of the arsphenamines, bismuth compounds, tartar emetic and Frei antigen has not produced any untoward toxic effects. Thus combined lesions may be treated at the same time. The known precautions of blood counts, examination of the urine and clinical observations of the patient should certainly be carried out.

Nine patients for whose lesions a definite diagnosis was not possible were given sulfanilamide or a derivative. When no healing of the lesion took place, it was found on further investigation not to be a chancroid.

From the foregoing data it would seem that the use of sulfanilamide and its derivatives is indicated as a therapeutic test. If the lesion fails to heal, other diagnostic means and other therapy should be tried.

SUMMARY AND CONCLUSIONS

1. A series of 175 consecutive ambulatory patients with chancroid infection were treated with sulfanilamide and sulfathiazole.

2. The identification of the Ducrey bacillus on smears stained by the Unna-Pappenheim method (methyl green pyronine) was found to be the most important single diagnostic criterion of chancroidal infection.

3. Ducrey bacilli were identified in 88.5 per cent of the cases in routine smears from chancroidal ulcers.

4. The intradermal reaction to Ducrey vaccine proved to be specific and was found positive in about 95 per cent of cases.

5. The Ducrey vaccine test is more important when the results are negative, to exclude active chancroidal disease. When the reaction is positive it often indicates a past, healed infection.

6. The reaction to Ducrey vaccine remained positive in all cases after complete healing of the active lesion had taken place.

7. Chancroidal buboes were present in about 42 per cent of the cases.

8. Sulfanilamide was administered orally to 150 patients for fourteen days; a total of 45.6 Gm. (760 grains) in divided doses was found adequate.

9. Sulfathiazole was administered orally to 25 patients for ten days; a total of 20 Gm. (300 grains) in divided doses sufficed.

10. All definitely proved chancroidal infections healed with chemotherapy.

11. Surgical measures of any description were contraindicated and found unnecessary.

12. Aspiration of large inguinal abscesses was found sufficient in some cases. Spontaneous absorption of small abscesses took place in 5 cases during chemotherapy.

13. Reinfections occurred in 5 cases, and there was 1 questionable relapse; all the lesions healed promptly with a second course of chemotherapy.

14. Local application of sulfathiazole powder healed superficial chancroidal ulcerations. In 2 patients a relapse occurred, but the lesion responded promptly to oral therapy with sulfathiazole.

15. More than half (54 per cent) of the patients in our series were found to be infected with two, three or four venereal diseases during their observation.

16. Sulfonamide therapy may be used as a therapeutic test in the differential diagnosis of chancroid.

125 Worth Street.

Man Contrives His Own Undoing.—There was a time when men were content to grind their corn and use the flour as it came. It was good flour, but brown. They wanted it white, for reasons of social prestige. . . . So an important part of the grain was removed, just as the husk was removed from the rice by polishing, or as fat is cut from the meat by the butcher, or as much of the value of food is removed by refrigeration, by canning and by various modern devices whereby we make stale food appear fresh. Thus man contrives his own undoing. He pays the miller to remove the best part of the wheat, pays the scientist to find out what he's done, pays the chemist to make it for him again, and pays the miller to put it back. And we say that man's greatest asset in his power of reason.—Atkinson, Miles: *Behind the Mask of Medicine*, New York, Charles Scribner's Sons, 1941.

PHYSICAL FITNESS OF CHILDREN FROM DIFFERENT ECONOMIC LEVELS IN CHICAGO

MARTHA CRUMPTON HARDY, Ph.D.

H. H. BOYLE, M.D.

AND

ALVAH L. NEWCOMB, M.D.

CHICAGO

For a number of years the Elizabeth McCormick Memorial Fund has been interested in the accumulation of a body of factual information on the general health and dietary practices of preschool and school age children in the Chicago area. Its regular health education program centers around a periodic examination by a pediatrician, followed by family consultations with a nutritionist. Approximately 1,500 children from six hundred families, largely from the low income levels, are examined each year in connection with this program.

In 1939, with the assistance of the Work Projects Administration,¹ a study was begun of the records of 10,000 children who had been enrolled in the Fund's health supervision classes during the preceding decade, and plans were made for examining during the next two years a large number of children from widely different economic levels. Since then more than 7,200 children from three thousand nine hundred families have been examined with one or both parents present.

This article presents observations on the incidence of certain health problems among 6,438 children who were examined between January 1939 and October 1940. The group was approximately equally divided as to sex: 3,253 boys and 3,185 girls. Their ages at the time of examination ranged from 2 years to 18 years, 88 per cent being between 5 years and 14 years of age.

SELECTION OF CASES AND CHARACTERISTICS OF COMMUNITY AREAS REPRESENTED

Contacts with the families were channeled through the public schools, private nursery schools and district offices of private and public welfare agencies. With the cooperation of the public school authorities, schools in distinctly different types of neighborhoods were selected and all children attending them (and their siblings) were given an opportunity to have the examination. Some of the best and some of the poorest neighborhoods in Chicago, representing various national and racial groups, were included. The proportion of pupils examined in these schools ranged from 33 per cent to 75 per cent of the children attending these schools. In general, parents in the better neighborhoods appeared more interested in having their children given the health check-up than those in poorer districts.

To insure an adequate sample of the relief population, special examining centers were established in settlements and in field houses in the parks. All families on the rolls of the Chicago Relief Administration having preschool or school age children who lived within walking distance of these centers were invited by letter. Examinations were always by appointment and on the condition that a parent would be present.

Districts of the city represented in the study included community areas in which the child population is

reported as densest according to the 1934 census data for Chicago.² A spot map showing the distribution of the selected neighborhoods is given in figure 1. Schools are indicated on the map by black squares and other centers by black circles. General conditions in these selected areas, as reflected by relief status, color and nativity of the families, and infant mortality and communicable disease morbidity rates,² present a wide distribution of economic and health problems. In approximately a fourth of the areas conditions were better than the average for total Chicago and in a fourth of them they were poorer.

The economic status of the families included in the study was determined from information given by the parent with regard to regularity of employment, type of occupation, extent of financial assistance from relatives or agencies, length of time on relief and annual income. Three broad economic categories were used: economically independent, marginal and relief.

Families that reported regular employment with no financial assistance from relatives or agencies during the two years prior to the examination (70 per cent had never received financial assistance) and a stable type of occupation at the time were classified as "economically independent." The majority of the reported incomes ranged from \$2,000 to \$4,000, 2 per cent being as high as \$10,000.

Families that were receiving financial assistance from either private or public agencies at the time of the examination were classified as "relief." The principal sources of relief were, in the order of frequency, Chicago Relief Administration, Mothers' Pension of the Juvenile Court of Cook County and United Charities of Chicago.

The "marginal" class included families not on relief at the time of examination but that were on the WPA rolls or had been on relief at some time during the past two years; families in which there was a history of irregular or seasonal employment or of recent employment after an extended lay-off; families living with relatives or friends and receiving some assistance from them, and families in which the wage earners were employed at low wage levels.

THE PHYSICAL EXAMINATION

Immediately preceding the physical examination a health history of each child was obtained from the parent—usually the mother. This history included information on antepartum care, delivery, infant feeding, general development, health habits and practices, immunization, an account of illnesses and accidents, a detailed inventory on the child's regular dietary and pertinent comments on leisure time activities, attitude toward school and playmates, management difficulties and methods used to control the child. Other information concerned a family history of tuberculosis and diabetes, clinic registrations and facts with regard to living conditions. This history, together with the record of certain body measurements (height, weight and, in some instances, girths) was in the physician's hands at the time the child appeared for the examination.

Young children and boys were examined without clothing; older girls were stripped to the waist. Results were dictated by the physician at the time of examination and recorded by an assistant on a prepared schedule. At the completion of the examination the physician

From the Elizabeth McCormick Memorial Fund.

1. Assistance in the collection and analysis of the data for this report was given by the Work Projects Administration (O. P. 65 1-54 2334)

2. Health Data Book for 75 Local Community Areas of the City of Chicago, Chicago, Chicago Board of Health and Tuberculosis Institute, 1939

stated his judgment on the child's general health status and listed the specific conditions for which remedial care was recommended. The record was then checked by him for accuracy and the mother was advised as to the child's health needs.

Reports on the physician's recommendations were sent to the medical case workers of the relief agencies involved, and the responsibility for follow-up care was assumed by the agency. Parents in the economically independent and marginal classes were advised to take the child to his private physician for the care recommended.

At the beginning of this study a special effort was made by the medical staff to agree on the meanings of descriptive terms used and the conditions under which certain types of recommendations would be made. All correctable defects were cited, regardless of whether or not there were facilities for taking care of them. For example, the need for orthodontia was indicated wherever it was noted, although it was doubtful whether families on relief or those on low incomes could arrange for this type of care.

Seven physicians participated in the investigation—four regular staff pediatricians and three who were engaged for this special study. The latter spent at least one week in observing and conferring on procedures used by the medical staff and in making examinations under their direction. A few weeks after the program was under way a number of children seen by one pediatrician were reexamined by him and by several other physicians on the same morning. To avoid any misunderstanding, the parents and teachers of the children who were selected for this recheck were informed of the plan and the reasons for it. Each physician was given a complete copy of the child's health history but no information on the previous examination. Variations in observations and ratings and in recommendations were later discussed in conferences and a further effort was made to insure comparable procedures and standards. Schedules were so arranged that each physician saw children from different economic levels.

Body measurements were taken under the personal supervision of a trained anthropometrist. Steel tapes, measuring boards and scales and the technic for using them were checked from time to time to insure comparability of results. Approximately 1 out of every 4 children examined was photographed without clothing or in shorts.

NATIONAL ORIGINS, SIZE OF FAMILY AND HOUSING

With few exceptions the children in this study were American born. Thirty-five per cent of them were of native white parentage, which is the proportion reported for total Chicago in the 1934 census. Nineteen per cent were of Negro and 5 per cent were of Mexican parentage.

The size of family varied directly with the economic classification, but large families (8 or more children)

were found at all income levels and among both the white and the Negro. The average number of children per family was 3. Among the Mexican families the average was 6 children, but the largest families were noted among the white native born. The range in size of family was from 1 child to 17 children. The largest family in the white economically independent class had 9 children, in the Negro 11.

Children examined were most frequently the first or second born in their families, but 3 per cent were the

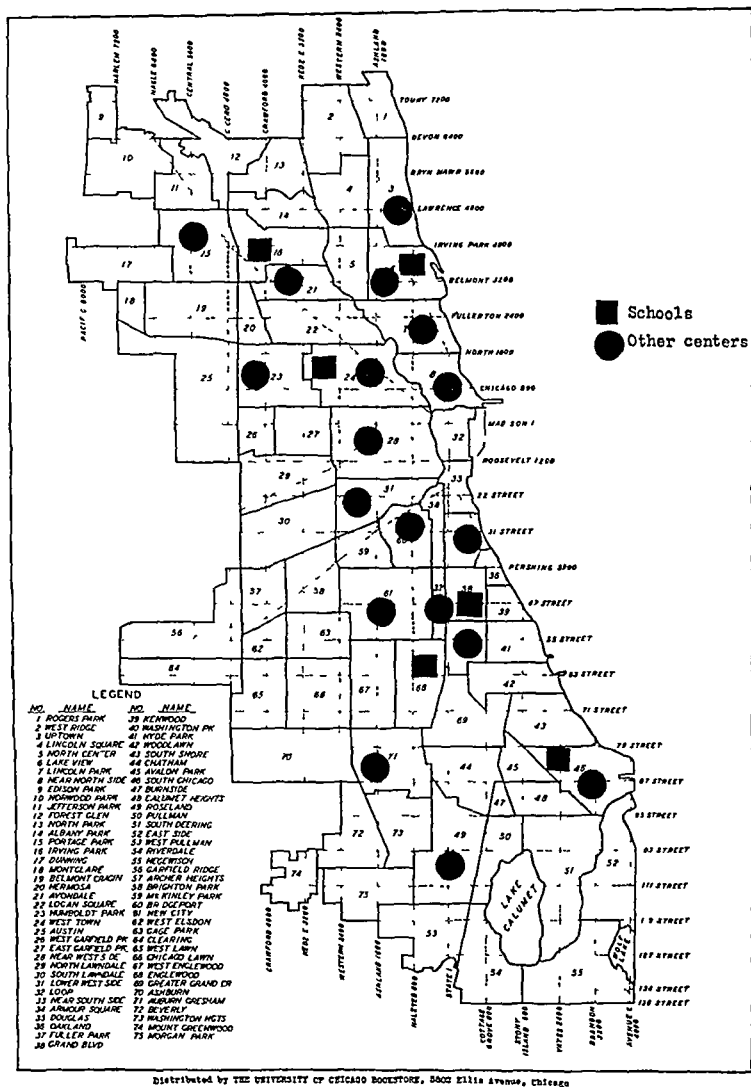

Fig. 1.—Distribution of selected neighborhoods in health study made between January 1939 and October 1940.

eighth or later born. All birth orders from first to seventeenth were represented.

The overcrowded conditions under which some of the families lived are strikingly evident in the sleeping arrangements for the children. In some instances as many as 6 children were reported as sleeping in one bed. The degree of crowding has been estimated in two ways: (1) the average number of persons per room in each household and (2) the number of bedfellows with whom the children examined were reported to sleep. Frequencies of various degrees of crowding among the different racial and economic groups are briefly summarized in table 1. Crowding was apparently more common among the families included in this study than

was noted in the sample population of Chicago in the National Health Survey (1935-1936).³ The National Health Survey reported that 25 per cent of the white families in Chicago were living more than one person per room and 46 per cent of the Negro families. Figures presented in table 1 show this degree of crowding in 35 per cent of the white and 67 per cent of the Negro families. However, these variations are to be expected, since the survey sample included all types of households, and the present study was restricted to those having children.

FAMILY HISTORY OF TUBERCULOSIS OR DIABETES

A history of tuberculosis in the families in this study was reported for 15 per cent of the white, 17 per cent of the Negro and 10 per cent of the Mexican children. This history was noted as frequently among the economically independent class as among those on relief—among the white, 15 per cent in the economically independent class and 14 per cent in the Chicago Relief Administration class; among the Negro, 19 per cent in

physical fitness are given in table 3. The weight status according to percentage deviations from standards for height and age is graphically shown in figure 2.

Medical Care as Related to Economic Status and Color.—Medical care was recommended in cases in which specific conditions were judged to deviate from the normal to the extent that professional remedial services were advisable or in which symptoms or history indicated a need for further examination or treatment.

Types of health problems most frequently noted by the physicians are given in table 2 for white and Negro children according to economic status of the family. Data on the Chicago Relief Administration cases are presented separately in the last two columns of the table.

There is no evidence in these observations of an association between need for medical care and economic status. The outstanding fact indicated is that most of the children examined, regardless of the family income level, needed medical attention. Sixty per cent of the children were in need of medical care, and their parents were so advised by the examiner.

* Housing index based on number of families, sleeping arrangements on number of children examined

† Mexican total includes 10 nonrelief families

the economically independent and 15 per cent in the Chicago Relief Administration class. A grandparent or other near relative was reported more frequently in this history than a parent or sibling

Incidence of diabetes in the family was higher among the white than among the Negro (12 per cent of the white against 8 per cent of the Negro) and among the economically independent than among the relief class (16 per cent of the economically independent white against 8 per cent of the relief). These comparative differences are statistically significant

CONDITIONS FOUND ON PHYSICAL EXAMINATION

Results of the examinations are presented in terms of conditions requiring remedial professional care, general health ratings and the incidence of certain types of deviations from normal. The types of professional services most frequently needed are summarized in table 2. Figures on the incidence of certain conditions such as poor muscle tone, insufficient fat padding, round shoulders and flaring ribs and low ratings on general

Inspection of table 2 shows that a slightly larger proportion of white children in the independent class than in the total relief class required medical attention—59 per cent in the independent and 55 per cent in the relief. Comparisons with the marginal income class suggest that more medical care was needed by this class than by the others, but here again differences are not large—64 per cent of the marginal against 59 per cent of the independent and 55 per cent of the relief class.

Health problems were reported more frequently in the case of Negro than of white children. The incidence was higher in each economic category, the smallest variations occurring in the Chicago Relief Administration comparisons. In the independent class 59 per cent of the white compared with 70 per cent of the Negro were advised to have medical attention, and among the Chicago Relief Administration class 61.5 per cent of the white against 68.7 per cent of the Negro. The evidence here is conclusive.

The results give no indication of an association with nativity of parents. Differences between the white of native born parentage and other white rarely exceeded 1 per cent in either direction. Figures cited in table 2 for total white cases are practically the same as those for native white parentage cases.

3. Adequacy of Urban Housing in the United States as Measured by Degree of Crowding and Type of Sanitary Facilities; National Health Survey, Sickness and Medical Care, Bulletin 5, Washington, D. C., U. S. Public Health Service, 1938

Types of Medical Care Needed.—The remedial services advised by the physicians in their recommendations to the parents were for many different conditions. Those listed in table 2 represent the types of health problems observed in at least 1 out of every 100 children examined. Services most frequently needed were for orthopedic care. Among white children remedial services for abnormalities of posture or defects of the spine were advised in 12 per cent of the children and for abnormalities of the foot in 15 per cent of them.

The second ranking problem of medical care was that of ear, nose and throat conditions. Fourteen per cent of all children examined were in need of this type of medical attention, exclusive of surgery. In approximately 2 per cent of the children this care was advised because of ear conditions. Removal of tonsils and adenoids was recommended only if considered necessary by the pediatrician after a careful review of the history of infections. In 13 per cent of the children having tonsils, removal was advised.

Other problems in order of frequency related to conditions of eyes, skin, genitourinary system, heart and lungs. Remedial services for eyes, ears and nose were judged on inspection at the time of the examination and on the history—the eyes by general inspection, the ears and nose with an otoscope. Tests of visual acuity and of hearing were not made. The incidence of eye conditions needing professional care was 9 per cent; that of heart conditions 2 per cent, and that of lung conditions 2 per cent.

In general, these various types of medical care were needed no less by children from the higher economic level than by those from the low levels. Neither in frequency nor in type is there evidence of a relation between need for care and economic status.

Medical Care as Related to Age Level.—With the exception of eye conditions, incidence of medical attention varied little with age. In the case of eyes, as age increased there was a progressively larger proportion recommended for care. For example, the proportions in the independent class needing attention were 2 per cent at the preschool level, 5 per cent at ages 5-9 years, 10 per cent at ages 10-14 years and 14 per cent at ages 15-19 years; in the relief class these proportions were 2 per cent, 9 per cent, 11 per cent and 15 per cent respectively.

At all age levels the most frequent type of remedial service needed was orthopedic care. Corrections of abnormalities of the foot in the case of white children were recommended at different age levels in the following proportions, ranging from youngest to oldest: 17 per cent, 15 per cent, 13 per cent and 18 per cent.

Ear, nose and throat conditions again rank second in order of frequency, regardless of age level. Figures on recommendations for removal of tonsils and adenoids according to the age of the child differ little from those previously given for total cases. Among white children having tonsils, removal was advised in 9 per cent of the youngest children, 19 per cent of the next age level, 12 per cent of the next older and 8 per cent of those 15 years of age or older. Corresponding percentages for Negro children were 7, 13, 8 and 9.

These results tend to emphasize the widespread need for health service by children of all ages and different income levels.

Dental Care as Related to Economic Status and Color.—The majority of the children in the study (58 per cent) were reported to need dental care, exclusive of prophylaxis, and the lower the economic level the larger the proportion requiring corrective work. Undoubtedly these figures are an underestimation of the actual problem of dental care, since they are based on inspection by a physician rather than by a dentist. They serve to indicate the extensiveness of the problem among different economic classes and all age levels.

Significant differences between the white independent class and the relief class with respect to dental care are clearly indicated. Comparisons with the marginal class likewise show a consistent trend which justifies the conclusion that high incidence of dental defect is associated with low income level. Proportions of white children in each economic class who were advised to have corrections made were 52 per cent in the independent, 59 per cent in the marginal and 68 per cent in the relief—70 per cent in Chicago Relief Administration group.

Fig. 2.—Weight status of 4,768 white children in Chicago, examined between January 1939 and October 1940, according to economic class, in terms of percentage deviations from the Baldwin-Wood standard.

These figures include all conditions of teeth judged by the physician to require professional attention.

Decided variations in the teeth of white and Negro children were apparent, a larger proportion of the white at each economic level having dental defects. Among the Negro children, the proportions according to economic class were 37 per cent in the independent, 46 per cent in the marginal and 52 per cent in the relief class. The relation to economic level is suggested, but the differences here are not statistically reliable.

At the time of the examination the physician reported the number of carious teeth observed. Analyses of these records show an average of more than one carious tooth per white child, 45 per cent having at least two teeth with cavities and 4 per cent having as many as eight carious teeth. In each economic class some cases with a large number of dental defects were reported. The averages for white children were as follows: independent class one and thirty-five hundredths carious teeth, marginal two and five hundredths teeth and relief two and three tenths teeth.

Need for dental care was noted at all ages but was least in evidence at the preschool level. Among children under 5 years of age, 23 per cent were reported to have dental defects. At all age levels the association

with economic status was indicated, though the differences were not always large.

Comparisons of white 10 year old children, one of the largest age groups, show an average of one and five tenths carious teeth per child in the independent, one and eighty-eight hundredths in the marginal and two and thirty-eight hundredths in the relief class. The proportions at this age having carious teeth were 56 per cent in the highest economic level and 65 per cent

the other extreme, 38 per cent were rated as in relatively poor condition—that is, their health status was definitely unsatisfactory.

In the judgment of the physicians, children from the lower income levels were less robust than those from the economically independent level. Health ratings of those in the independent class show a significantly larger proportion in excellent condition and a smaller proportion in poor condition. Ratings indicative of

and 73 per cent in the lower levels. The range was from no caries to eleven affected teeth and was the same for the high and low income classes.

Health Ratings as Related to Economic Status and Color.—Immediately after the examination, the detailed observations were summarized by the physician in the form of a rating, which described his impression of the child's general physical condition. Analyses of these ratings show that only 6 per cent of the children examined were described as in excellent health. At

excellent health were three times as frequent at the economically independent level as at the relief level and twice as frequent as at the marginal level. Frequencies of high and low health ratings, which describe the most and least robust, by economic class, are given in table 4.

Differences between the marginal and relief classes were neither consistent in direction nor statistically significant. There is little indication in these ratings that the children in the marginal class were either more or less healthy than children in the relief class.

The trend of the ratings was the same at all age levels, and in the case of children between the ages of 5 years and 14 years the differences are statistically significant. It seems safe to conclude that children in the economically independent class were in better general health than the other children of like ages.

There was no association between high or low ratings in health and differences in age. The physical condition of the young children was considered by the physician as neither better nor poorer than that of the older children. For example, the proportion at each age level rated as in excellent health, in order of increasing age, was 6 per cent, 6 per cent, 7 per cent and 4 per cent.

White children were found to be in better condition than the Negro or Mexican children. Ratings indicative of good health were reported more frequently in the case of white children and poor conditions less often than in either of the other groups.

Incidence of Certain Physical Conditions.—Comparative results on the incidence of certain physical deviations from normal are summarized in table 3. The first section of the table reports incidence of the conditions among white, Negro and Mexican children without regard to economic status. The center sections present the data according to economic level. In the last section results are shown for the Chicago Relief Administration group.

The high frequencies noted, among both white and Negro children from different economic classes, of flabby muscles, poor posture, round shoulders, bow legs, defective feet and carious teeth offer definite proof of the unsatisfactory physical condition of a large proportion of these urban children. In at least 1 out of every 4 children examined, regardless of the economic level of the family, some of these defects were observed.

Defects of teeth outrank all other physical deviations among the children in this study, but the incidence of many others is high. In order of frequency, exclusive of teeth, the most common conditions were bow legs 45 per cent, poor posture 44 per cent, round shoulders 31 per cent, flabby muscles 26 per cent, deficient fatty tissue 26 per cent, flaring ribs 23 per cent and pale mucous membrane 20 per cent. The figures cited for bow legs represent various degrees of bowing, relatively few cases showing an extreme degree.

A number of these conditions appeared to be associated with the economic level, but on the whole the incidence was high in each income class. The results with respect to fatty tissue in the case of white children clearly warrant the conclusion that a deficiency in fat padding was most frequent at the lowest income level and least frequent at the economically independent level.

Underweight in Relation to Economic Status and Age Level.—A distribution of weight status in terms of percentage deviations from expected weight for age, sex and height, according to Baldwin-Wood tables, is presented in figure 2 for white children at different economic levels. Cases exactly at standard (zero deviations) have been thrown half to the underweight and half to the overweight frequencies. Inspection of the graph will show that the weight status of approximately a fourth of the children is suggestive of poor nutrition—they were underweight 10 per cent or more or overweight 20 per cent or more.

Analyses of the underweight children (those 10 per cent or more below the norm) reveal a significantly smaller proportion in the independent class below standard than in the other economic classes. While the comparative differences are not large, they give evidence of the higher incidence of underweight at the low income levels than at the economically independent level. The trend of these results is in agreement with that indicated in the doctor's reports on insufficient fat padding.

Among the total children examined 20 per cent were found to be underweight; among the economically independent class 16 per cent and among children in the Chicago Relief Administration class 22 per cent. While the standards used are open to criticism from a number of standpoints, in the light of figures from other investigations based on the same standards the present results are probably an underestimation of the extent to which the children in this study deviated from an optimum condition.

Within the age range which included the majority of the children (2-14 years) there is a systematic increase with advancing years in the proportion of underweight among white children. Differences are not large but are progressive and, in the case of the relief class, are statistically significant. For example, in the

TABLE 4.—Percentage of Children Having High and Low Health Ratings According to Color and Economic Class

	High Health Ratings		Low Health Ratings	
	White	Negro	White	Negro
Economically independent	13.4%	8.6%	21.0%	34.9%
Marginal.....	4.9%	3.9%	41.7%	54.5%
Relief total.....	3.4%	2.0%	47.7%	47.9%

white relief class, 6 per cent of preschool age children were underweight, 16 per cent of those in the 5 to 9 year age level and 24 per cent of those 10 years and over. No consistent trend was observable in the results on Negro children.

At all age levels and in all groups a larger proportion of girls than boys was underweight. In the total group, 25 per cent of the girls and 15 per cent of the boys were as much as 10 per cent below the expected weight standard.

ILLNESS AS RELATED TO ECONOMIC STATUS

A history of illnesses and accidents together with comments from the mother on severity and age at the time of the illness was obtained prior to the physician's examination. A check list of diseases was used to assist the mother in recalling the history. Questions on the frequency of colds, coughs, sore throat, headaches, constipation and nervous habits were included.

Analyses of the records on illness indicated an average of three different types of sickness episodes per child in each economic class and racial group. The results yield no evidence of a greater amount of sickness among the children from the low income levels. Among 10 year old white children 11 per cent were reported to have had six or more illnesses—the proportion in the economically independent class was 14 per cent, that in the relief class 7 per cent.

Injuries by an accident of some type were reported in 18 per cent of the cases, the figures being identical for white and Negro and practically the same for all economic classes. Approximately half of the children

had had a surgical operation—57 per cent of the white and 42 per cent of the Negro children.

As would be expected, removal of tonsils and adenoids was the most frequent type of operation reported. The proportion in the white group having had this type of operation was 40 per cent, in the Negro group 18 per cent; among the Chicago Relief Administration cases the figures were 33 per cent in the white group and 18 per cent in the Negro; among the marginal class 32 per cent in the white and 20 per cent in the Negro group. The incidence of removal of tonsils and adenoids among white children 10 to 14 years of age varied directly with economic status, but only in comparisons of the independent with the relief class is the difference statistically significant.

A history of frequent colds, coughs or sore throats was reported in a third of the cases. The incidence did not appear to be related to economic level or color. The proportions having this history were as follows: in the independent class, 31 per cent of the white and 40 per cent of the Negro children; in the marginal class, 33 per cent of the white and 38 per cent of the Negro; in the Chicago Relief Administration class, 35 per cent of the white and 33 per cent of the Negro.

Records on nervous habits among these children give no indication of differences between the economic classes with respect to incidence of enuresis, nail biting, speech difficulties or like habits. The majority of the children in each income class and racial group had no history of these conditions. The frequency in percentage among white children as reported by the mothers is given in table 5.

IMMUNIZATION STATUS AS RELATED TO ECONOMIC LEVEL AND AGE

The need for immunization was estimated on the basis of the physicians' recommendations concerning smallpox vaccination and the Schick test. Inspection of the records showed that 21 per cent of the children in the study had not been vaccinated and 34 per cent had not been immunized against diphtheria.

The incidence of the need for immunization was closely associated with age, recommendations for this protection being most frequent at the younger ages. Among children under 5 years of age 55 per cent had not been vaccinated and 29 per cent had not been immunized against diphtheria. At ages 10 years and older the figures were 13 per cent needing smallpox vaccination and 34 per cent the Schick test.

TABLE 5.—Incidence of Nervous Habits in White Children of Different Economic Classes

	Economically Independent (1,247)	Marginal (537)	Chicago Relief Administration (1,666)
Enuresis	10.1%	16.2%	15.4%
Nail biting	26.9%	25.6%	22.7%
Speech difficulties	10.7%	9.0%	6.3%
Other habits	23.0%	16.4%	12.7%

At the relief level a much larger proportion of the children were not made immune to smallpox or diphtheria than at the higher income levels. The figures with respect to children under 5 years of age according to economic class are given in table 6.

These results are disappointing in the light of the active campaign carried on in Chicago over a number of years for the immunization of preschool and school children. The results are, however, in agreement with reports from other public health programs. In a recent

evaluation of a six year program in Tennessee⁴ in which preschool immunization was emphasized, the results from the last year (1936) show that 43 per cent of the white 6 and 7 year old children at the time of their first examination had not been immunized against diphtheria. During the entire period of preschool supervision, only 31 per cent of the white children of these

"	71%	37%
"	74%	41%

ages on entering school were found to have been vaccinated against smallpox.

DIETARY PRACTICES IN RELATION TO ECONOMIC STATUS AND COLOR

A detailed account of the findings on dietary practices of the children included in this study is to be reported in the near future. As they are definitely a part of the health picture presented in this paper, the trend of the data with little explanation of the technic employed will be given at this time.

Adequacy of protective foods in the diet was evaluated in terms of the number of weekly servings of these foods. Classifications were based on the four diet levels outlined by the U. S. Department of Agriculture (1936),⁵ namely (1) liberal diet, (2) moderate cost adequate diet, (3) minimum cost adequate diet and (4) restricted diet for emergency use. In this study diets below the restricted diet level were treated as a fifth classification. Attention should be called to the fact that diet levels 3 and 4 are both below the recommended dietary allowances of the Committee on Food and Nutrition of the National Research Council (1941).

The level of the diet was closely associated with the economic status. Poor diets were found more frequently in the relief class than in the higher income classes and good diets much less often. The figures with respect to weekly servings of fruits and vegetables, including potatoes, offer striking evidence of this relationship. Diets having less than the minimum of eighteen servings of these foods a week, which is below the level of the restricted diet for emergency use, were noted in the following proportions: independent class 10 per cent, marginal income class 32 per cent, Chicago Relief Administration class 64 per cent.

In general, the diets of Negro children were less adequate than those of white children. Variations were consistent and statistically significant at different economic levels, but the differences were greater at the higher levels. Records on consumption of fruits and vegetables, including potatoes, show the following proportion below the minimum standard: independent—white 8 per cent and Negro 23 per cent; marginal—white 25 per cent and Negro 46 per cent; Relief Administration—white 62 per cent and Negro 69 per cent.

4. Walker, W. F., and Randolph, Carolina R.: School Health Services: A Study of the Programs Developed by the Health Departments in Six Tennessee Counties, Commonwealth Fund, 1941, pp. 119 and 120, 1, 11, 87 and 88.

5. Carpenter, Rowena Schmidt, and Stielcing, Hazel K.: How to Fit the Family Income, U. S. Department of Agriculture, Service Bulletin 1757, 1936.

The results clearly reflect the need for health education among the urban families included in this study. It is significant that, when judged on a standard currently considered very low, namely restricted diet for emergency use, 10 per cent of the children in families who could afford to buy adequate amounts of fruits and vegetables were getting them in amounts below this level, which is not sufficient to maintain good health. When compared with the dietary allowances of the Committee on Food and Nutrition, the fruit and vegetable intake of more than half of the children (51 per cent) from these economically independent families was found to be below the recommended allowances.

SUMMARY AND CONCLUSIONS

Analyses of the health records of 6,438 children representing widely different income levels and various types of community areas in Chicago, who were examined by pediatricians in 1939 and 1940, furnish factual evidence on the extensiveness of the health problem at different economic levels. The results on physical fitness may be briefly summarized as follows:

1. Need for professional health services:

(a) Children from nonrelief families were no less in need of professional care than those from relief families.

(b) Variations between the different income levels with respect to incidence and type of medical care needed were small and not statistically significant.

(c) The incidence of health services advised by the physicians was as follows:

(1) Sixty per cent of the children were in need of medical care.

(2) Fifty-eight per cent of them were in need of dental care (according to observations of pediatricians).

(3) Thirty-four per cent had not been immunized against diphtheria (29 per cent of the children under 5 years of age).

(4) Twenty-one per cent had not been vaccinated against smallpox (55 per cent of the children under 5 years of age).

2. Association of low income with poor physical conditions which may not have required professional services:

(a) Ratings indicative of poor general health were reported more frequently and of good health less often in the lower income classes.

(b) The incidence of carious teeth was higher at the lower income levels.

(c) Underweight was noted more frequently in the low income classes.

(d) Observations of insufficient amount of fat padding, poor posture, round shoulders, flaring ribs and bow legs was more frequent at the low income levels.

3. Health differences between white and Negro children:

(a) A larger proportion of the Negro than of the white children were in need of medical care.

(b) Ratings indicative of poor general health were reported more frequently and of good health less frequently in the case of Negro than of white children.

(c) The incidence of underweight and of other signs of unsatisfactory physical condition was higher in the Negro than in the white group.

4. Adequacy of diet:

(a) Adequacy of diet was directly associated with economic status. Poor diets were more frequent at the lower levels and good diets at the higher income levels.

(b) The intake of fruits and vegetables was inadequate at all income levels—39 per cent of the children were having less than the minimum requirements for the protection of health.

(c) Inadequate diets were noted more often among the Negro than among the white children.

Evidence of the need for health supervision and health education at all economic levels is strikingly shown by the results of this study. Poor nutrition is clearly manifest in a composite of flabby muscles, underweight, pale mucous membranes, round shoulders, fatigue posture, bow legs, knock knees, flat feet, carious teeth and inadequate diets. At no income level is the general health picture satisfactory, but at the low levels it is definitely unsatisfactory.

848 North Dearborn Street.

FOCAL INFECTION

CHARLES H. SLOCUMB, M.D.

MELVIN W. BINGER, M.D.

ARLIE R. BARNES, M.D.

AND

HENRY L. WILLIAMS, M.D.

ROCHESTER, MINN.

For a long time it had been recognized that acute inflammatory disease in a certain region of the body could produce secondary inflammation in some other region. Nevertheless, it was not until after the work of Billings and his co-workers that the conception that chronic, often symptomless, infections of low grade, localized in various parts of the body, could produce disease elsewhere in the body, began to receive general recognition from members of the medical and dental profession in this country. Rosenow¹ stated "The scope of this influence may be judged by the voluminous literature on focal infection that has appeared [since the publications of Billings] throughout the whole civilized world, and in which striking benefit to patients suffering from various diseases and also failure of others to improve have been reported." Although earlier diligence was directed largely to the reporting of the "striking benefits," there has lately appeared a tendency to focus the regard on the "failure of others to improve." This tendency seems to have reached a culmination in the recent paper of Reimann,² in which he found no evidence to support the conception that such an entity as focal infection exists.

Although it is admittedly difficult clinically to distinguish sharply the stage in which chronicity begins, there seems to be a tendency on the part of physicians to admit the validity of the conception of acute foci of infection without demur. There also seems to be great reluctance on the part of some investigators to admit that toxins or bacteria from a site of long-standing infection can enter the circulatory system to set up secondary disease in other regions. The explanation for this suggested difference in bodily reaction does not seem to have been satisfactorily explained by the opponents of the theory of "focal infection."

Read before the New England Otolaryngological Society, Boston, Jan. 8, 1941.

There are probably few physicians who have not observed a sudden and puzzling relief of a patient's symptoms following removal of a "chronic" focus of infection. Such improvement may occur with sufficient infrequency, however, to justify recent expressions of doubt as to the etiologic significance of the focus and also doubt as to whether or not a causal relationship had existed between the focus of infection and the disease which apparently yielded to the therapeutic procedure.

Although bacteriologists³ have been extremely critical of proof obtained on the basis of clinical evidence alone, the debate and controversy arising from their several attempts to conclude the discussion of focal infection by exact scientific methods constrain us to avoid this particular aspect of the subject and to attempt evaluation of the conception of focal infection on the basis of clinical observations alone. To do this we feel that we must limit ourselves to observations of certain well defined disease entities and attempt evaluation of such clinical improvement as may or may not seem to have occurred following removal of a focus or foci of infection. We shall confine ourselves to a consideration of the effects of removal of such foci of infection as occur in the field of otolaryngology and we shall try to assess the effect of removal of foci of infection in heart disease, chronic infectious arthritis and glomerulonephritis, since these three conditions are representative of those in which removal of foci of infection has been said to be of clinical benefit.

HEART DISEASE

For the purpose of the present consideration, heart disease has been subdivided into several clinical entities.

Coronary Sclerosis.—This condition, depending as it does on certain irreversible changes in the walls of the coronary arteries, would seem to us to be unlikely to be diminished by removal of foci. The thesis that toxic absorption from foci of infection over a long period can produce such chronic degenerative changes as sclerosis of the coronary vessels is impossible either to prove or disprove on the basis of data available. Coronary thrombosis,⁴ it has been suggested, in certain instances may have a bacterial background and if so would then seem to depend on transient bacteremia⁵ such as is associated with acute infections of the upper part of the respiratory tract, and on acute exacerbations of chronic foci of infection somewhere in the organism.

Hypertensive Heart Disease.—This condition has been the subject of much clinical discussion and experimentation since the work of Goldblatt and may be considered to be in a state of flux. It will not be considered in this paper.

Syphilitic Carditis.—This disease has a well authenticated cause; thus it can be eliminated readily as a product of focal infection.

Acute Pericarditis.—This condition is usually bacterial in origin and in all probability depends for its appearance on the presence of transient bacteremias⁶ from acute and possibly chronic foci.

Chronic Pericarditis.—Chronic pericarditis is the end result of an infection rather than an active process itself and can be dismissed from consideration herein.

Cor Pulmonale.—Where cor pulmonale (or dilatation of the right side of the heart secondary to obstruction of the pulmonary circulation) depends for its origin on chronic asthma with secondary emphysema, it obviously cannot be caused by focal infection. When chronic emphysema is secondary to chronic bronchitis, however, the role possibly played by infection in the tonsils and paranasal air spaces cannot be dismissed so summarily. Larsell and Fenton,⁷ in demonstrating the lymphatic connections between the paranasal sinuses, the tonsils and the peribronchial lymph nodes, suggested an etiologic relationship between chronically infected tonsils or sinuses and the ultimate development of chronic infection of the tracheobronchial tree. Elimination of such a focus of infection must be obtained before an irreversible process, such as emphysema with pulmonary hypertension, has taken place, because elimination of the focus of infection after the development of such a symptom complex could offer but little toward amelioration of the condition.

Rheumatic Carditis.—The evidence for and against focal infection as an etiologic agent in rheumatic carditis must be considered carefully, because the earlier enthusiasm displayed by some investigators for such a relationship seems to have subsided. In reviewing earlier literature on the influence of tonsillectomy on the recurrence of rheumatic fever, Cohn suggested that the period of observation following operation usually was too short to allow adequate evaluation of results, since it had been found that the percentage of recurrence increases with the passage of time. May Wilson⁸ in her recent monograph included a careful study of 413 rheumatic children, 247 of whom had tonsils removed either before or after the first rheumatic infection. The remaining 166 children served as controls. Wilson came to the conclusion that removal of the tonsils seems to have no effect on either the appearance or the recurrence of rheumatic activity. It seemed to her that the value of tonsillectomy for rheumatic children was proportional to its influence on the general health of the child. Our own opinion concerning the influence of the tonsils on rheumatic fever is in accord with that of Wilson.

On the basis of our clinical experience we feel, therefore, that in heart disease focal infection can be considered to be a factor only in an occasional case of coronary thrombosis or acute pericarditis, and in the small group of cases in which emphysema and pulmonary hypertension result from chronic bronchitis secondary to infection in tonsils or sinuses.

We also believe that, in the presence of an old valvular lesion, removal of septic tonsils (especially following quinsy), removal of badly infected teeth or drainage of seriously diseased sinuses must be done with circumspection. Elliott⁹ has shown that surgical intervention in very marked foci of infection might produce bacteremia which, exerting an adverse effect on an injured valve, might be the starting point for subacute bacterial endocarditis. The practice of preceding surgical intervention with infections in the presence of chronic valvular injury with chemotherapy by sulfonamide compounds can be recommended, we believe, on theoretical, experimental and clinical grounds.

CHRONIC INFECTIOUS ARTHRITIS

In chronic infectious arthritis a condition of admittedly unknown causation is encountered. Hench¹⁰ summarized all the arguments which have been made for and against the microbic theory of origin of this disease. He found that the argument in favor of the theory rested on twenty-one points, each of which for reasons given was discounted by opponents of the theory. Hench formed two conclusions, one on the basis of his work as a clinical investigator, the other on his experience and needs as a practicing physician. "As a clinical investigator," he wrote, "I must conclude that the cause of atrophic arthritis is still unknown and that the evidence for infection, although very impressive, is incomplete. Invoking the privileges of a clinical investigator I cannot and need not now decide for or against the microbic theory with any finality. As a practicing physician, however, I cannot wait until the evidence is complete. The exigencies of practice force one to express an opinion one way or another. . . . Therefore, as a practicing clinician I have committed myself to the microbic theory." With this statement we are in accord.

It is our opinion that the treatment of chronic infectious arthritis should be individualized. A systemic disease, "it is no more a disease of joints than typhoid fever is a disease of Peyer's patches" (Pemberton). No single form of treatment is adequate, and in evaluating the results of treatment the physician must rely on objective improvement rather than on the patient's subjective relief, lest he be misled by the psychic effects on the patient inherent in any therapeutic measure.

Many physicians regard elimination of foci of infection as the measure of first importance in treatment.¹¹ Others have not been favorably impressed by results of removal of such foci. Miller¹² believed that the removal of foci was included with other therapy, a practice which clouded the issue. He considered it unfortunate that removal of chronic foci of infection should be considered by so many physicians or investigators to be the first and major treatment, since this procedure had resulted in the loss of much valuable time which might have been used more profitably in other directions.

However, the fact that removal of chronic foci of infection is not followed by rapid or notable relief does not invalidate the importance of eradication of such foci. Several workers have insisted that results of removal of foci of infection may be poor because often more than one focus is present. Foci are too often imperfectly removed, and indeed it is impossible to eradicate them if the focus is not local but is diffuse (for example, nasopharyngitis). Last, too much may be expected of removal of foci of infection in the presence of irreversible articular pathologic change.

Buckley¹³ at times noted most remarkable improvement, and even cure, to result from removal of foci and expressed the belief that following removal of foci of infection complete recovery has occurred a sufficient number of times to indicate that such foci may be of etiologic importance in arthritis. The changing views of one authority on arthritis were reported by Cecil and

Angevine.¹⁴ In 1927 Cecil and Archer¹⁵ reviewed 200 cases of chronic infectious arthritis in which focal infection seemed to play a major role in the causation of the disease. In 1938, however, in an analysis of 200 new cases of rheumatoid arthritis, Cecil and Angevine came to the conclusion that although undoubtedly there are instances of chronic infectious arthritis which result from focal infection as far as typical rheumatoid arthritis is concerned, it would appear that chronic focal infection plays a comparatively unimportant role. In the same year in a quarter-century survey of focal infection, Bierring¹⁶ approved the more conservative attitude which has developed with reference to hasty diagnostic conclusions and radical removal of suspected foci of infection, but he considered that clinical and bacteriologic evidence had afforded definite confirmation of the fundamental conception of focal infection and felt that perchance focal infection may yet become the medical guide of the future.

On the basis of our own experience, we feel that, given a patient who has chronic infectious arthritis and in whom a definite focus is present, the focus should be eradicated as soon as the patient's general condition warrants surgical treatment. The decision as to the optimal time to remove a focus should rest with the clinician rather than with the laryngologist. Although we feel that focal infection should be eliminated as early as possible when chronic infectious arthritis is present, we prefer a period of observation to elapse before surgical intervention is attempted, so that we can be sure that progression of symptoms is under control. We prefer that the patient's condition is such that fever is absent or slight, that anemia is improving and that loss of weight has ceased. With attention to these factors, we rarely encounter a flare-up in symptoms of chronic infectious arthritis after surgical elimination of a focus of infection has been carried out. Although it is admittedly impossible to assess accurately the improvement produced by removal of a focus of infection from a patient who, at the same time, is receiving other forms of therapy, we believe that we can expect real diminution in symptoms of definite clinical importance to result from such removal for 5 per cent of patients whose infected tonsils are the only discoverable focus. The same results can be obtained for approximately 4 per cent of patients whose sinusitis seems to be the source of infection.

We encounter many patients who report diminution in symptoms of chronic infectious arthritis after any type of surgical intervention or even general anesthesia has been carried out, but the improvement persists for from three to seven days and then is gradually lost. Improvement which we feel to be of clinical importance is pronounced and is maintained permanently following surgical eradication of a given focus. For the remainder of the patients the operation is of value only for the effect it may have in improvement of the general health of the patient.

GLOMERULONEPHRITIS

Because many of the toxins which develop in the body as results of human or bacterial metabolism are eliminated through the kidney, it might be expected that if the conception of focal infection had an actual

physical counterpart the kidney would be likely to be affected by the supposed toxins produced. No experimental work yet done has provided an explanation for the exact pathogenesis of acute glomerulonephritis as it occurs in man. In the recent work of Schwentker and Comploier,¹⁷ for example, rabbits received emulsions of homologous kidneys alone and in combination with streptococcal toxin. Control animals received toxins alone. In the blood of these rabbits complement fixing antibodies were found which were similar to complement fixing antibodies found in the blood of a majority of patients who had scarlet fever. This work suggests that cytotoxins originate autogenously when the kidney is injured by toxins, but it does not explain why it is that clinically recognizable nephritis develops among some persons while they have scarlet fever, whereas among others it does not.

By "acute glomerulonephritis" is meant acute renal disease in which there is definitely impaired renal function as evidenced by the loss of large amounts of albumin in the urine, retention of nitrogenous products in the blood, bleeding from the parenchyma of the kidneys, severe oliguresis or, in some instances, anuria. It is generally recognized that a patient who has "acute nephritis" may die during an acute attack of the disease, that such a patient's kidneys may become completely healed, or that his condition may eventually develop into chronic glomerulonephritis.

Woods and Binger¹⁸ estimated the etiologic agents in 61 cases of acute glomerulonephritis at the Mayo Clinic. These patients previously had shown no evidence of renal disease. Woods and Binger found that in 84 per cent of the cases the condition had developed during acute inflammation of the upper part of the respiratory tract, including cases in which the diagnosis was acute coryza, acute mastoiditis, acute tonsillitis or acute pharyngitis. Fourteen of the patients in this series had undergone tonsillectomy and 7 had undergone mastoidectomy while the nephritis which they had was in a comparatively active stage. After elimination of the focus of infection a noticeable improvement in the renal disease was noted. It was suggested that elimination of these foci of infection was largely responsible for the favorable and encouraging results in this series of cases, because neither death nor chronic nephritis ensued in any of the 21 cases mentioned in which the acute focus of infection was eliminated.

It is widely accepted that chronic glomerulonephritis is not a progressive disease which starts from one acute attack of nephritis but that it is caused, rather, by repeated or continued toxic assaults on the kidneys which originate in acute or chronic foci of infection. The chronic changes resulting from necrosis of tissues are irreversible and when changes are widespread we are aware that little can be done toward cure of chronic nephritis. Of the patients suffering from chronic nephritis who come to us with intermittent exacerbations of the acute phase, more than 80 per cent have evidences of chronic infections about roots of teeth, in the tonsils or in the sinuses. We feel that the clearing up of such foci as soon as possible not only shortens the convalescent period of the acute episode but, in addition helps to protect the patient from further damage to the kidney.

CONCLUSIONS

Assay of the probable importance of focal infection from the clinical standpoint alone as it concerns the three clinical entities of heart disease, chronic infectious arthritis and glomerulonephritis reveals that we progress from tepidity toward relative enthusiasm to whole-hearted acceptance of the conception of focal infection. From the clinical standpoint we find it impossible to distinguish clearly among the acute focus the subacute focus, the chronic focus with acute exacerbation or the true chronic focus, because the transitions between these several states are not sufficiently abrupt. It seems certain that the conception of focal infection is of definite clinical usefulness and that it is unreasonable to expect removal of foci of infection to eliminate the fibrous end result of tissue necrosis. Viewed from this standpoint, such papers as the one of Cecil and Angevine seem to lose much of their force antagonistic to this conception. In a "reevaluation" of the conception of focal infection it would seem the more logical procedure to consider it in relation to a single disease entity rather than to become lost in generalities, and it would seem wise to consider, along with the results secured, the stage of the condition present and the pathologic processes involved.

Results of the study suggest that the type of condition being seen by a given clinician tends to influence his attitude toward the conception of focal infection.

OBSERVATIONS ON THE PROPHYLACTIC USE OF SULFANILAMIDE ON RHEUMATIC PATIENTS

WITH A REPORT OF ONE DEATH

DAVID DUDLEY STOWELL, M.D.

AND

WILLIAM H. BUTTON JR., M.D.

NEW YORK

With the advent of sulfanilamide therapy it was natural that it should be tried in rheumatic fever. Despite the lack of proof that the hemolytic streptococcus is the etiologic factor in the disease, it has been postulated that the beta hemolytic streptococcus acts as a catalytic agent to start off the rheumatic cycle. It was soon shown by Swift, Moen and Hirst¹ and Massell and Jones,² independently, that not only is sulfanilamide of no value in active rheumatic fever but that it is definitely harmful. In January 1939 two papers appeared on the prophylactic use of the drug in susceptible rheumatic subjects, in one of which Thomas and France reported encouraging results in an adult group of ambulatory patients and in the other Coburn and Moore³ were just as encouraging about a group of children in a convalescent home. With this in view, it was decided to try the drug on ambulatory rheumatic children carrying on their normal activities. The first

part of the study was not started until the last of January 1940, owing to lack of technical assistance, and was terminated the end of May.

SELECTION OF PATIENTS

The subjects for the first study were all taken from the Children's and the Adolescents' Cardiac Clinics of Roosevelt Hospital. Every child had had a definite rheumatic attack within the past two years, i. e. polyarthritis, carditis or chorea (chorea had to be accompanied by some other rheumatic stigma before it was accepted as being due to rheumatic fever). Because of the unusual toxicity of sulfanilamide in active rheumatic fever, we excluded any child who we thought was active at the time. In the group used, the average age was 11 years and the average weight 83½ pounds (37.8 Kg.), as opposed to the control group in which average age was 9½ years and average weight 72 pounds (32.7 Kg.). The distribution of sexes in the two groups was the same, being about 50 per cent of each. Each group was made up of 14 children with approximately the same cardiac histories and social status. The only difference between the groups was that the controls lived at some distance from the hospital and were unable to come in regularly for check-ups on the blood and urine.

PROCEDURE

In both groups a preliminary test on the urine, blood count, sedimentation rate determination (Westergren), electrocardiogram and roentgenography or fluoroscopy of the chest were done. Following the dosage used by Drs. Coburn and Moore, we gave 1.5 Gm. of sulfanilamide in three divided doses to the children weighing less than 55 pounds (24.9 Kg.) and 2 Gm. to those weighing more than 55 pounds. Each child was given a printed set of instructions directing him to report any sign of toxicity immediately to the social worker or to the doctor in the accident room. Each child was instructed to report to the laboratory twice a week for the first three weeks for a check-up on the hemoglobin and the white blood cell count and to report weekly thereafter. At every visit the urine was tested for bile. Sedimentation rates were done at least once a month. The control group was not followed so closely.

RESULTS OF FIRST STUDY

Of the 14 children taking the drug, 7 did well and no further comment is needed. There were 2 cases of rash on a dosage of 0.6 Gm. three times a day which disappeared when 0.6 Gm. was given only twice a day. The drug was stopped entirely in 5 cases. In 1 of these a drug rash persisted even after the dosage had been reduced. In another, the rash was so severe in three days that it was deemed foolhardy to continue even on a reduced dosage. There is some uncertainty about 1 of these 5 children because he had a febrile incident in the home and stopped the drug himself. In the remaining 2 cases the drug was stopped because of the reduction of the polymorphonuclear cells; in 1 the cells dropped to 26 per cent on the twenty-first day and the other to 30 per cent at the end of eleven weeks. We decided to stop the drug when the polymorphonuclear count dropped to 30 per cent and were always concerned when it got below 45 per cent. At such times we did daily counts. There were 4 cases in which this occurred.

Of the 14 children in the control group, 7 remained well. Three had respiratory infections necessitating bed

rest but showed no signs of rheumatic activity. Two children had questionable rheumatic activity and 2 had a definite rheumatic flare-up.

The number the first year was small but we wished to gain some knowledge of the difficulties involved in using the drug on ambulatory children before undertaking a larger group.

PROCEDURE OF SECOND STUDY

In the fall of 1940 we started the study again on a larger scale. We decided to use any child or adolescent who had a definite diagnosis of a previous rheumatic episode regardless of when it occurred, as long as the condition was inactive at the time that the drug was started. We feel that any child who has had an attack of rheumatic fever is subject to a recurrence until well past adolescence, at which time the danger is less apparent. To be of any real value, a prophylactic measure of this kind would, of necessity, have to be used yearly until the patient reached the age of 17 or 18 years. For this reason all we required for inclusion in this group was a previous diagnosis of rheumatic fever.

The same method of taking white and red blood cell counts twice a week for three weeks, then once a week thereafter, was used. Sedimentation rates were also determined at the beginning and at least once a month thereafter. Since we had run into no difficulty with the urine the previous year, this test was eliminated.

RESULTS OF SECOND STUDY

Thirty-two patients were started on the drug early in December. The results are summarized here and more detailed histories are given at the end of this article.

Eighteen patients were treated without incident. One boy was readmitted to the ward three weeks after he started taking the drug. However, his condition may not represent a reactivation, since it was active by laboratory tests six weeks before admission to the group, though inactive by the same tests two weeks before admission. His probably was a condition of continued activity rather than a fresh flare-up of an inactive case. Three patients did not cooperate in getting regular blood counts. Nausea developed in another, necessitating stopping of the drug. Rash developed in 3 cases and the drug had to be discontinued, as lowering the dosage did not relieve the symptoms. In 5 cases there was a lowering of the blood count to levels which we considered alarming. In 3 of these 5 it was necessary to stop the drug altogether.

The last patient, a boy aged 12 years, was found to have an enlarged heart, electrocardiographic changes and an elevated sedimentation rate in July 1938. He had chorea in December 1938. On Dec. 27, 1940 he was started on sulfanilamide 0.6 Gm. three times a day. He came regularly for his blood counts and was doing well. His blood count on Jan. 22, 1941 showed a red blood cell count of 4.7 million, a white blood cell count of 5,550, polymorphonuclears 50 per cent, eosinophils 2 per cent, band forms 7 per cent, lymphocytes 43 per cent and mononuclears 3 per cent. On January 25 a sore throat and an elevation of temperature developed. He did not come to the hospital, as advised, but stopped the drug and saw his local physician, who treated him symptomatically for one day. The following day he received 0.6 Gm. of sulfanilamide and the next day was admitted to the hospital, having had 0.3 Gm. before he came. When he arrived at the hospital sixty hours after the onset of symptoms he had exudate with a

few ulcers on his throat and a temperature of 105 F. The blood count showed normal red cells and 300 white cells, with only 1 per cent polymorphonuclears. The sulfanilamide level was 1.86 mg. per hundred cubic centimeters. Blood culture showed hemolytic *Staphylococcus aureus* and three days later hemolytic *Staph. aureus* and pneumococcus type III, at which time the sulfanilamide level was 1 mg. per hundred cubic centimeters. His course was steadily downhill; the temperature never went below 105 F. At no time did he have more than 1 per cent polymorphonuclears. He died on the fourth day despite transfusions twice a day, pentnucleotide, yellow bone marrow extract and liver extract. For the hemolytic *Staph. aureus* he received bacteriophage. As a last effort he was given intravenous sodium sulfathiazole three hours before death. The cause of death was acute agranulocytosis with secondary infection of the blood stream with hemolytic *Staph. aureus* and pneumococcus type III. Unfortunately permission for an autopsy or bone marrow study was not granted.

COMMENT

Since the beginning of the study we had been concerned with the possibility of sulfanilamide toxicity if given over a long period of time, even in small doses. We had hoped to avoid any toxicity by careful observation of the patients and frequent laboratory check-ups of the blood. We selected only children whose parents we felt would cooperate with us in seeing to it that the patients reported regularly. Despite this, we found that the human equation militated against us and that in some cases from one to two weeks would go by before a child would report for blood counts or for clinic appointments. Also, when unforeseen conditions arose the parents would not consult us but would use their own judgment as to how to treat the situation. The most efficient and sympathetic aid was given by the social worker and the laboratory technician.

With these precautions, in the first year one half of the patients had to give up using the drug because of some toxic reaction. In the second year, when the drug had been used but two months, 9 patients out of 32 had to discontinue using it, and 1 death occurred which was attributable to the sulfanilamide. After the death we had many consultations as to whether or not the study should be continued and finally decided to stop the use of the drug prophylactically in our clinic.

We feel that the drug should not be used as a prophylactic for the ambulatory rheumatic patient because in our experience, while subject to rigid precautions, it failed. We do not feel that a simple reduction in the dosage is the answer, although the toxicity of the drug was diminished considerably thereby. We feel that no large group of children can take the drug in any dosage over the necessary eight to ten winters without some mortality from its use.

CONCLUSIONS

1. Sulfanilamide can be a lethal drug when used prophylactically on the rheumatic patient.
2. At the present state of knowledge the drug should not be used in ambulatory rheumatic children and adolescents.

BRIEF SUMMARIES OF CASES IN WHICH SOME DIFFICULTY WAS ENCOUNTERED

In cases 1, 2 and 3 the only difficulty was lack of cooperation in obtaining blood counts regularly.

A boy aged 7 years (case 4) was nauseated two days after taking the drug. He refused to continue even

on a reduced dosage. He had no change in the blood count.

Patient 5 had a rash at the end of thirty days on a dosage of 0.6 Gm. three times a day. The drug was stopped for five days with disappearance of the rash. Then she was started on 0.3 Gm. three times a day. She stopped the drug five days later because of headaches.

Patient 6, after one month on 0.6 Gm. twice a day, had swelling of the face and a drop in polymorphonuclears to 35 per cent. The next day the polymorphonuclears were 44 per cent, so the drug was continued. The day after that, he had a chill and the swelling of the face persisted, with polymorphonuclears of 50 per cent. Despite vagueness of symptoms, the drug was stopped and the swelling disappeared.

Patient 7 was taking 0.6 Gm. three times a day. A severe headache developed after the first dose, and after the second dose her teacher said that she was feverish, restless and had no appetite. The next day she took one more dose and in a short while had a recurrence of the severe headache and a punctate rash on the abdomen, so the drug was discontinued.

In case 8 on 0.6 Gm. twice a day, the polymorphonuclear cells dropped to 32 per cent the day after it was started. The drug was stopped for two days and the polymorphonuclears returned to 46 per cent. The drug was then given in doses of 0.3 Gm. three times a day. There was no further difficulty on this dosage.

Patient 9 took 0.6 Gm. three times a day. The polymorphonuclears fell to 28 per cent in five days. The next day, without change in the dosage, the polymorphonuclears rose to 56 per cent, but we reduced her dose to 0.3 Gm. three times a day. Two weeks later the polymorphonuclears were 45 per cent, at which time the study was terminated.

Patient 10 at the end of eight days had a generalized erythematous rash which disappeared twenty-four hours after the drug was stopped. He was then put on 0.3 Gm. twice a day and had no further rash, but two days later the polymorphonuclear cells fell to 37 per cent, and the next day the polymorphonuclear cells dropped to 31 per cent even though the drug had been stopped. Two days later they were still 31 per cent, although the total white cell count had risen from 4,100 to 6,700 cells.

Patient 11 on a dosage of 0.6 Gm. three times a day had polymorphonuclear counts fluctuating between 53 per cent and 38 per cent, necessitating frequent counts. The dosage was cut in half and the count was 37 per cent after six days, at which time the study was ended.

Patient 12 had a fall in polymorphonuclears to 35 per cent in ten days, but without stopping the drug he had a return to normal and continued without incident to the end of the period.

A girl aged 15 (case 13), weighing 115 pounds (52.1 Kg.), had taken the drug the previous year. At that time her polymorphonuclear cells fell abruptly to 30 per cent at the end of three months. This year, on a reduced dosage of 0.3 Gm. twice a day, she broke out after seven days in an urticarial rash on the hands and feet. There were no changes in the blood count. However, the drug was stopped. This case is particularly interesting because it may indicate a change of sensitivity to the drug.

Clinical Notes, Suggestions and New Instruments

THROMBOSIS OF THE INFERIOR VENA CAVA FOLLOWING PHYSICAL EXERTION

RUTH C. FOSTER, M.D.
STEPHEN W. BROUWER, M.D.

AND
CHESTER M. KURTZ, M.D.
MADISON, WIS.

During the past year we have had the opportunity to observe a case of obstruction of the inferior vena cava from shortly after the onset of the condition to the establishment of an apparently adequate collateral circulation. Because of the rarity of the condition and the unusual etiology, the case seems worth reporting.

REPORT OF CASE

A white girl aged 20, a physical education student, consulted the University of Wisconsin Health Service on Nov. 6, 1940 because of edema of the legs and enlarging abdominal veins. She had been well until July 29, 1940, when while "tumbling" she did a "back flip." At this time she felt "something pull" in the lower part of the back. There was little discomfort, however, until two days later, at which time there was aching in the small of the back, particularly when she was in the recumbent position, which was somewhat relieved by flexion of the thighs. The following day (August 1) the pain was present with walking or with straightening of the back, and the discomfort gradually became so severe that medical attention was necessary. A physician taped the lumbar region, but this seemed to aggravate the condition. On August 3 there was cramplike pain in the thighs, particularly the left, and general malaise associated with a slight febrile reaction. The symptoms became so severe that bed rest was necessary for the next three weeks. During this period the temperature rose to 102 F. The anterior aspect of the thighs became blue and somewhat edematous, the left more so than the right. There were repeated cramps in the legs which were associated with a temporary increase in the discoloration and were partially relieved by massage. When she attempted to stand, both the legs and thighs became swollen and blue, but elevation of the legs relieved this. At the end of three weeks the discomfort and fever had subsided and the patient was allowed out of bed. The legs then became hard and edematous, reaching what was considered to be two or three times their normal size. The edema was greatly relieved after a period of bed rest. On September 30 the patient was allowed to return to school. She then discovered for the first time that the veins of the right side of the abdomen were becoming large.

The past medical history was positive for measles, whooping cough and scarlet fever in early childhood. There had been repeated colds and sore throats. In 1937 an apical systolic murmur had been heard. On July 11, 1940 diseased tonsils had been removed and on July 25 a submucous resection was performed. Normal convalescence followed both surgical procedures.

On physical examination, November 6, the patient was well developed and well nourished and appeared to be in excellent health. There were no gross abnormalities of the eyes, ears, nose or throat. Fundoscopic examination gave negative results. There was a soft systolic murmur heard along the left sternal border and at the apex, present in all positions, but it practically disappeared with deep inspiration. The blood pressure was 124 systolic and 74 diastolic. Inspection revealed obvious enlargement of the superficial veins over the lower part of the chest, abdomen and upper part of the thighs, particularly on the right side. Over the lower half of the abdomen the venous blood flow was from below upward. The liver and spleen were not enlarged and ascites was not present. There was extensive edema of the legs and thighs with a bluish mottling, particularly on the left side, but the patient stated that there was much less edema than there had been a few weeks before.

From November 19 to December 4 the patient was in bed with mumps. During this period the edema was less pronounced and the superficial veins were less evident.

The patient has been observed periodically since. There has been a gradual decrease in the edema of the legs, but the abdominal veins have remained prominent. In February 1941 she was allowed to resume slowly the activities required of a physical education student. By June she was swimming, playing lacrosse and tennis and doing some modern dancing. The legs and ankles returned to their normal size and the edema would become evident only after a day of considerable physical exertion.

COMMENT

The diagnosis in this case was obstruction of the inferior vena cava, partial or complete. Extensive studies were made in December 1940 while the edema was still evident and again in June after the collateral circulation had apparently compensated for the obstruction. Blood studies including hemoglobin content, red and white blood cell counts, differential counts, serologic examination, determination of the blood sugar, nonprotein nitrogen, platelets, bleeding and coagulation time, chlorides, cholesterol, sedimentation rate, serum proteins and

Fig. 1.—Appearance of abdominal veins on Dec. 17, 1940.

the albumin/globulin ratio were within normal limits. Routine examinations of the urine were negative. Further renal studies, including dilution concentration tests, phenolsulfonphthalein and the urea clearance, were within the normal range. In December 1940 the cephalin-cholesterol test was 2 plus, suggesting slight impairment of liver function, although the galactose tolerance test was within normal limits and the plasma prothrombin time was 100 per cent.

Numerous roentgenograms of the spine and abdomen were made. The vertebrae were normal in position and there was no evidence of a tumor. Although careful neurologic studies gave repeatedly negative results, a spinal puncture was done in December. The spinal fluid was normal in every detail. In June 1941 roentgenograms of the abdomen were made to determine whether calcification of the vena cava had occurred, as has been reported in similar cases, but none was found.¹

Since Castellanos² has stressed the importance of visualization of the inferior vena cava for location of tumor masses, in

1. Keen, J. A.: A Case of Complete Obstruction of the Inferior Vena Cava, *Brit. M. J.* 2: 823-825 (Dec. 14) 1940.

2. Castellanos, Agustín, and Pereiras, Raul: La caviografía inferior; Comunicación preliminar, *Arch. de med. int.* 4: 362, 1938

June 1941 diodrast was injected into the distal portion of the great saphenous vein of the right foot. This showed the right common iliac vein well outlined. The shadow of this vein was traced to the level of the disk between the third and fourth lumbar vertebrae, above which it gradually faded. Some of the communicating veins lateral to the lumbar spine filled with diodrast so that dilated and tortuous collateral veins were visualized overlying the right side of the sacrum. Therefore, though this examination did not demonstrate definitely a complete block in the inferior vena cava, it showed a well developed collateral circulation. Roentgenograms of the chest and of the kidneys, including pyelograms, were all negative.

More detailed studies were made of the cardiovascular system. An orthodiagram in January 1941 showed the great vessels to be normal. The heart was within normal limits as to size and shape except for a slight dilatation of the left auricle posteriorly and to the right. Because of the murmur and the characteristic orthodiagram, it was felt that a mitral lesion existed. It is probable that this lesion had been present previously, since a systolic murmur had been noted in 1937. Ortho-

Fig. 2.—Appearance of abdominal veins on June 11, 1941.

diacoscopy was repeated in June and showed no change. In January 1941 the electrocardiogram showed slight elevation of the ST segments in all four leads which had practically disappeared in May 1941. One month later the ST segments had again become elevated. In February 1941 venous pressures determined by the direct method were 17 cm. of water in the antecubital vein and 21 cm. of water in the ankle vein. In June determinations by the indirect method as described by Eyster³ were 7 cm. of water in the wrist vein and 21 cm. of water in the ankle vein. Also on this date the circulation time was studied by the use of 10 per cent calcium gluconate. The circulation time from the antecubital vein to the tongue was seven seconds and from the ankle vein to the tongue was ten seconds. The circulation time from the antecubital vein to the lung by the ether method was four seconds.

COMMENT

In a review of 314 cases of obstruction of the inferior vena cava Pleasants⁴ has classified them according to their etiology as follows: obstruction due to (1) thrombosis primarily, (2)

new growths within the inferior vena cava, (3) nonmalignant disease of the abdomen, (4) new growths outside the vena cava, (5) kinking of the inferior vena cava, (6) congenital obliteration and (7) ligation. One hundred and seventy-one fell into the first group, and of these 41 were due to specific infectious diseases, 8 were a complication of chlorosis, 45 followed puerperal sepsis, 17 were due to local inflammatory foci, 18 were from direct trauma, 2 resulted from injury associated with overexertion and 40 were of unknown etiology.

We believe that the obstruction in this case was due to thrombophlebitis following overexertion. Several points in the history are of interest and are fairly significant. There was a history of recent surgery to the nose and throat at which time badly diseased tonsils were removed. Ochsner and DeBakey⁵ emphasize that "trauma whether operative or non-operative predisposes to thrombophlebitis either directly as a result of injury to vessels or indirectly as a result of injurious substances derived from destroyed tissue." Also there is a remote possibility that a temporary bacteremia followed tonsillectomy with injury to the vascular system. The history of additional trauma due to overexertion is fairly definite. It was during a "back flip" that our patient felt something give way in her back, and all her symptoms dated from that episode. Though such an etiology is doubtless rare, there are several cases in the literature presenting somewhat comparable histories. Pleasants⁴ mentioned 2 cases, 1 in which thrombosis followed a forced march and another in which there was "overexertion followed by severe lumbar pain and symptoms of obstruction." Shattock⁶ described the condition in a medical student aged 24 who had severe lumbar pain after running a race. This was followed by edema of the legs and enlargement of the superficial veins. An autopsy on this patient twenty-five years later showed occlusion of the inferior vena cava extending from below the portal vein to the renal veins. In our case it seems reasonable to suppose that the sudden strain from strenuous physical exertion caused an injury to the wall of a vessel which may have been weakened as a result of recent surgery.

The clinical course was typical of a gradually developing caval obstruction. The first complaint was severe lumbar pain, which was later associated with fever, both symptoms probably being due to thrombophlebitis. This was followed by massive edema of the legs and thighs, which slowly disappeared as the collateral circulation developed.

For a detailed description of the collateral circulation in obstruction of the inferior vena cava, the reader is referred to Pleasants' monograph.⁴ Our patient was not seen until her acute symptoms had subsided, so all studies on her must be considered from that standpoint. If these could have been made during the acute phase they would have been more significant. However, in view of the edema described, the extensive collateral circulation and some evidence of possible hepatic involvement three months after the onset of the illness, it is probable that the obstruction occurred in the upper third of the vena cava.

Bay, Gordon and Adams⁷ have reported electrocardiographic changes with experimental occlusion of the vena cava in dogs. They found deviation of the ST segment which persisted with the obstruction. It is interesting to note that in the case here reported, ST segment deviation constituted the only abnormal electrocardiographic condition.

The prognosis of inferior caval obstruction is good if the underlying pathologic condition is not progressive and the obstruction is slow enough to permit an opportunity for development of an adequate collateral circulation. There are reports in which a patient has survived for as long as forty years. We feel that our patient will be able to teach physical education as she had planned and that she should be perfectly well so long as she keeps her physical activities within reasonable limits.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

RADIOEAR MASTERPIECE ACCEPTABLE

Manufacturer E A Myers and Sons, 306 Beverly Road, Mount Lebanon, Pittsburgh

The Radioear Masterpiece, a carbon microphone aid, was examined by the Council and was found to consist of the following parts

Microphone number M 1665
Intensifier A 1434
Battery case
Miniature crystal receiver R 2576
Molded earpiece
Bone conduction oscillator B 1304

The microphone is disk shaped, $2\frac{1}{2}$ inches in diameter, $\frac{5}{16}$ inch thick, weighing approximately 2 ounces, fitted with spring clip for attaching to clothing. The battery case and intensifier are

of molded bakelite. The battery case carries two 1.5 volt cells, size C, number 935, for air conduction, or three similar cells for bone conduction. With two cells the weight is approximately $6\frac{1}{2}$ ounces and with three cells approximately 7 ounces. The earpiece is of molded bakelite, to be fitted into the ear cavity. The receiver is of the miniature magnetic type,

Radioear Masterpiece

$\frac{5}{16}$ inch in diameter and $\frac{5}{16}$ inch thick. Receiver and earpiece together weigh approximately 0.4 ounce. The bone conduction oscillator is rectangular, $1\frac{1}{2}$ by $\frac{3}{4}$ by $\frac{5}{8}$ inch, weighing approximately 0.8 ounce. All parts are mechanically well constructed. The fact that ordinary commercial dry cells can be used and are easily replaceable is a distinctly advantageous feature.

Battery Consumption—With the two cell battery of 3 volts for air conduction the currents drawn are as follows

Control barely on	25 milliamperes
Control half on	30 milliamperes
Control fully on	40-50 milliamperes

With the three cells, 4.5 volts for bone conduction,

Control barely on	35-40 milliamperes
Control fully on	70-75 milliamperes

Internal Noise—Direct comparison of the internal noise with the noise from an audiometer of the buzzer type indicates that the noise level is of the order of 20 to 25 decibels above the normal ear threshold. This would not be a disturbing element in cases of deafness in which the threshold of hearing is below normal by this amount. There is no "feed back" noise in the instrument under conditions of use.

Amplification—Using two deaf subjects, the amplifications at discrete frequencies from 128 to 4,096 cycles were measured audiometrically. The receiver of a Western Electric 2-B audiometer was set in a capsule of sponge rubber and the threshold of the subject was measured with the receiver thus enclosed held to the ear. The thresholds were again determined with the transmitter of the hearing aid laid on the sponge rubber capsule and the earpiece inserted in the ear of the subject. The differences between the two thresholds were taken as the gain in decibels afforded by the aid. Results obtained by the two observers in repeated tests were fairly consistent. The average gains in decibels shown with the air conduction receiver were as follows:

Frequency	128	256	512	1024	2048	4096
Gain	8	7	16	13	8	none

Articulation Tests—The instrument was found to give satisfactory results in these tests.

The Council voted to accept the Radioear Masterpiece for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1941, p. 551)

The following dosage forms have been accepted

Tablets *Thiamine Hydrochloride Endo*, 1 mg, 3 mg, 5 mg
Prepared by Endo Products, Inc., Richmond Hill, N. Y.
Solution *Thiamine Hydrochloride Endo*, 1 mg per cc, 6 mg per cc, 10 mg per cc, 15 mg per cc, and 30 mg per cc in 1 cc *Ampuls*.
Each cubic centimeter of solution contains 10 mg of benzyl alcohol in sterile distilled water.
Prepared by Endo Products, Inc., Richmond Hill, N. Y.
Solution *Thiamine Hydrochloride Endo*, 10 mg per cc, in 10, 25, and 50 cc vials, 30 mg per cc in 10, 25, and 50 cc vials, 50 mg per cc in 5, 10, and 25 cc vials. Each cubic centimeter of solution contains 10 mg of benzyl alcohol in sterile distilled water.
Prepared by Endo Products, Inc., Richmond Hill, N. Y.

NICOTINIC ACID (See New and Nonofficial Remedies, 1941, p. 555)

The following dosage forms have been accepted

Tablets *Nicotinic Acid*, 25 mg
Prepared by the International Vitamin Corp., New York.
Tablets *Nicotinic Acid*, 50 mg
Prepared by the International Vitamin Corp., New York.
Tablets *Nicotinic Acid*, 100 mg
Prepared by the International Vitamin Corp., New York.

SUSPENSION OF EPINEPHRINE IN OIL, 1:500-N. N. R. (See New and Nonofficial Remedies, 1941, p. 255)

Epinephrine in Oil, 1:500-Smith-Dorsey—A brand of suspension of epinephrine in oil 1:500-N. N. R.

Manufactured by The Smith-Dorsey Co., Lincoln, Neb. No U. S. patent or trademark.
Ampuls *Epinephrine in Oil 1:500-Smith-Dorsey*, 1 cc. A suspension of 2 mg powdered epinephrine crystals in 1 cc of peanut oil.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1941, p. 247)

The following dosage forms have been accepted:

Ampoules *Ephedrine Sulfate Solution Endo*, 0.05 Gm ($\frac{3}{4}$ gr.), 1 cc.
Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.
Tablets *Ephedrine Sulfate Endo*, $\frac{3}{4}$ grain.
Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

CYCLOPROPANE (See THE JOURNAL, May 31, 1941, p. 2505, and the Supplement to New and Nonofficial Remedies, 1941, p. 5)

CYCLOPROPANE (OHIO CHEMICAL & MFG CO)—A brand of cyclopropane-U. S. P.

Manufactured by Ohio Chemical and Manufacturing Co., Cleveland. No U. S. patent or trademark.

SODIUM MORRHUATE (See New and Nonofficial Remedies, 1941, p. 501)

The following dosage form has been accepted.

Vial *Sodium Morrhuate 5% and Benzyl Alcohol 2%*, 5 cc. Each cubic centimeter contains 0.05 Gm of sodium morrhuate and 0.02 Gm of benzyl alcohol in aqueous solution.
Prepared by The Lakeside Laboratories, Inc., Milwaukee.

CAFFEINE WITH SODIUM BENZOATE (See New and Nonofficial Remedies, 1941, p. 173).

Hint, Eaton & Co., Decatur, Ill.

Ampuls *Solution Caffeine with Sodium Benzoate*, 2 cc. An aqueous solution containing in each 2 cc of caffeine with sodium benzoate, U. S. P., 0.5 Gm ($7\frac{1}{2}$ grains).

TETANUS TOXOID, ALUM PRECIPITATED (See New and Nonofficial Remedies, 1941, p. 470).

Parke, Davis & Company, Detroit

Tetanus Toxoid, Alum Precipitated (Refined)—Marketed in packages of two 1 cc vials (one immunization treatment) and in packages of one 10 cc vial (five immunization treatments).

THEOPHYLLINE WITH ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1941, p. 583).

The following dosage form has been accepted

Ampule *Solution Aminophylline*, 20 cc, 0.48 Gm ($7\frac{1}{2}$ grains).
Prepared by The Lakeside Laboratories, Inc., Milwaukee.

SATURDAY, DECEMBER 20, 1941

EMERGENCY MEDICAL SERVICE FOR CIVILIAN DEFENSE

Under the section on Medical Preparedness in this issue of *THE JOURNAL* appears a special announcement from the Office of Civilian Defense on the relationship of emergency medical service to control centers. Last week the Council on Medical Education and Hospitals of the American Medical Association mailed to all hospitals reprints of two bulletins which have been issued by the Medical Division of the Office of Civilian Defense. These were published in *THE JOURNAL* under the heading of Medical Preparedness on August 30 and November 22. Those hospitals which have not received the bulletins should communicate at once with the Office of Civilian Defense. The outlines supplied, together with the information which appears in our current issue, give all the information needed for complete cooperation.

The significant steps include the following:

1. State and local authorities who have not done so should at once appoint state and local chiefs of emergency medical service in consultation with state medical societies.

2. State defense councils should instruct local chiefs of emergency medical service to complete a spot map which will show

- (a) Localization of all hospitals.

- (b) The number of emergency medical squads available

- (c) Sites for casualty stations in each section of the city.

3. Inventories should be made of bed capacity of hospitals inside and outside of cities, and the amount of expansion possible during an emergency determined.

4. Arrangements for transportation should be organized immediately in each district under control of the local civilian defense commander.

5. Staffs of hospitals and agencies for transportation should have a drill each week to perfect themselves for action in time of emergency.

Medical facilities from which the civilian defense organization in each state is being

developed are at the local level. In each community, therefore, the local chief of emergency medical service may set up medical advisory councils. He will, of course, utilize the local health department, experienced hospital administrators, representatives of the local medical society and the nursing organizations, and the American National Red Cross and other voluntary agencies. The full responsibility must rest with the local chief of emergency medical service and with his medical advisory council. All agencies must cooperate with this central organization. Attempts to delegate this responsibility or to divide it can result only in confusion and ultimately in disaster.

The medical profession may be relied on to accept the responsibility in this work, as in all other aspects of medicine, in relationship to the emergency. Obviously selection of physicians for work in the civilian defense agency should be left largely to men above the age of 45, since younger men will be required for the active needs of the military and naval services.

SPECIAL DIETARY FOODS AND THE LAW

Mr. Paul V. McNutt, Administrator of the Federal Security Agency, has recently promulgated regulations¹ governing the labeling of foods intended for special dietary purposes. The scope of these regulations is extraordinarily broad, apparently encompassing all foods and dietary supplements for which special claims are made or implied relating to health and disease. Included are vitamin and mineral preparations, staple foods fortified or supplemented with vitamins and other dietary elements, foods employed for infant feeding and foods offered as supplements in the management of obesity, malnutrition, food allergies, convalescence, pregnancy, anemias, lactation and disease. However, preparations administered in potent form solely as drugs for the treatment of disease are not subject to these regulations. For instance, addition of thiamine hydrochloride to a cereal will bring the cereal within the scope of the regulations, whereas a capsule containing 10 mg. of the same substance intended for use on a physician's prescription for the treatment of beriberi will presumably be considered a drug and not a food for "special dietary use."

Basically, the purpose of these regulations is to make available to the purchaser the fullest information concerning the vitamin, mineral and other special dietary properties of the article offered. Some method had to be found for expressing vitamin content, as well as the presence of other ingredients, in terms which would be readily understood by the ordinary purchaser. The

¹ Food, Drug and Cosmetic Act, Regulations under Section 403(j), Federal Register, Nov. 22, 1941.

Food and Drug Administration chose the minimum daily requirement as the basis for labeling. Foods to which these regulations apply are therefore required to state on the label the proportion of the minimum daily requirements furnished by a given amount. During the hearings on these regulations, discussion developed as to whether or not the optimum daily requirement should serve as the basis for the statements on the label instead of the minimum daily requirement. As the hearings progressed the impossibility of obtaining a convergence of expert opinion on what constituted an optimum daily requirement became apparent, whereas reasonable agreement was revealed among prominent students of nutrition on the range of values that could be related to the minimum daily requirements of the minerals and most of the vitamins. Unfortunately, the evidence adduced at the hearing was inadequate to permit the administrator to set a figure for nicotinic acid and some of the more recently isolated vitamins.

The public should know the nutritional properties of the food it purchases. When these regulations become effective, this information will be provided for the first time in terms than can be understood. The statement on a label that an article contains 1 mg. of riboflavin means little to the average purchaser; but when the label states, as it will under the new regulations, that a specified quantity of cereal X contains one half the minimum adult daily requirement of riboflavin the purchaser knows at least that additional riboflavin is needed. The Food and Drug Administration is to be commended for a job well done.

THE KENNY METHOD OF TREATMENT IN THE ACUTE PERIPHERAL MANI- FESTATIONS OF INFANTILE PARALYSIS

At the scientific meeting of the National Foundation for Infantile Paralysis held in New York early in December, consideration was given to reports on the Kenny method of prevention and treatment of the affected muscles. After the Committee on Research for the Prevention and Treatment of After-Effects had heard the reports from various experimental laboratories and clinics on their investigation of the subject, the committee adopted the following statement:

The National Foundation for Infantile Paralysis has supported studies of the Kenny technic under the auspices of the Medical School of the University of Minnesota and specifically under the direction of the Department of Orthopedic Surgery. The Minneapolis General Hospital was chosen for these studies, as beds were available and the necessary supervision was possible by members of the orthopedic staff and the Physical Therapy Department of the University of Minnesota.

The University Hospital rearranged one section of its building for the work, and the necessary equipment was installed. Since June 1941 work on the Kenny treatment of infantile paralysis during the early stage has been going on at both the University Hospital and the Minneapolis General Hospital under the per-

sonal supervision of Miss Kenny and her assistants trained in Australia. Most of the physical therapists of the Twin Cities and many from elsewhere have been working with Miss Kenny and acquiring a knowledge of her methods. The course for physical therapy technicians which has been started at the University of Minnesota includes training in the Kenny method.

The director of the Physical Therapy Department at the University Hospital and the Minneapolis General Hospital, aided by funds of the National Foundation for Infantile Paralysis, is making a detailed study of the method so that he and others may be able to continue with the teaching after Miss Kenny and her staff return to Australia.

It should be emphasized that patients under this treatment have been limited, with few exceptions, to those in the early or acute stage of the disease.

Since June of 1941 about 50 patients in the early stage of infantile paralysis have been treated in the Minneapolis General and the University Hospitals by Miss Kenny and her associates. The care of an almost equal number of patients in other hospitals has been supervised by her, but the actual treatment was carried out by the physical therapists in those institutions.

It is the opinion of this Committee on Research for the Prevention and Treatment of After-Effects of the National Foundation for Infantile Paralysis, after a study of the report of the workers at the University of Minnesota, that during the early stage of infantile paralysis the length of time during which pain, tenderness and spasm are present is greatly reduced and contractures caused by muscle shortening during this period are prevented by the Kenny method. The general physical condition of the patients receiving this treatment seems to be better than that of patients treated by some of the other methods during a comparable period.

It appeared to the Committee on Education and to the Committee on Epidemics and Public Health that the recognition of this method had many implications, particularly since it seemed likely that an outbreak of any considerable size during the spring and summer of 1942 would create a large demand for nurses and physical therapy technicians capable of administering the treatment. These committees therefore adopted the following report:

"It is the opinion of this Committee on Research for the Prevention and Treatment of After-Effects of the National Foundation for Infantile Paralysis, after a study of the report of the workers at the University of Minnesota, that during the early stage of infantile paralysis the length of time during which pain, tenderness and spasm are present is greatly reduced and contractures caused by muscle shortening during this period are prevented by the Kenny method. The general physical condition of the patients receiving this treatment seems to be better than that of patients treated by some of the other methods during a comparable period."

The Committee on Epidemics and Public Health and the Committee on Education of the National Foundation for Infantile Paralysis are aware of the implications of this statement as it relates to the application of the Kenny method in the early stage of infantile paralysis.

Health officers and physicians, including especially pediatricians, now have the intensified responsibility of early recognition of cases of infantile paralysis and the prompt application of appropriate nursing technics and physical methods to these patients.

During the past year the Kenny method has been observed with the aid of the National Foundation in several well recognized medical institutions. For best results this method involves care and the use of special skills under qualified medical supervision.

The Committee on Epidemics and Public Health and the Committee on Education recommend to the National Foundation for Infantile Paralysis that public health officials throughout

the nation be given as promptly as possible information which may be available regarding the nature of the Kenny technic and its integration with other measures of treatment, and the personnel available for its application in outbreaks of infantile paralysis.

The committees recommend furthermore that the training program of the National Foundation for Infantile Paralysis be expanded to provide additional training for considerable numbers of nurses and physical therapy technicians, and recommend expansion of the training program so as to make available additional personnel fully trained in the essentials and principles of the Kenny method.

The committees recommend furthermore that the Committee on Medical Publications of the National Foundation for Infantile Paralysis consider immediately the development of a concise manual providing the essential principles and details of the Kenny method and of other applications of hydrotherapy and physical treatment in the early stage of infantile paralysis.

The committees recommend that state health departments, health officials in larger communities, and other official agencies concerned with the care of infantile paralysis also develop a program to train personnel in the application of the Kenny technic in conjunction with other early treatment of infantile paralysis.

No doubt the National Foundation for Infantile Paralysis will make available in the near future the condensed manual of the technic referred to in these statements and also other information relative to the method so that it may be applied under the direction of competent physicians and specialists in orthopedic surgery as indicated in the individual case. It would, of course, be unfortunate if there should be any attempt to treat patients with infantile paralysis routinely without recognition of the fact that both the severity of the infection and the extent of the paralysis differ in each instance of the disease. Meanwhile the American people and the medical profession are fortunate in having an organization like that of the National Foundation for Infantile Paralysis capable of supporting controlled studies on every aspect of this serious disease and willing, through its board of trustees, to recognize the importance of consulting authoritative scientific information not only in the selection of projects for research but also in extending the results of such research to the patients who need them most. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has already pointed out that adoption of the Kenny technic represents an elaboration of well recognized principles in the treatment of acute paralysis and also the basis in scientific research on the physiology of the nervous system which explains the value of the technic as practiced. If there is any revolutionary element in the Kenny technic, it consists in its abandonment of early rigid splinting and the adoption of continuous and meticulous hydrotherapy and physical therapy to maintain the function of muscles which still have nerve supply at the highest possible point, at the same time producing increased comfort for the patient. No doubt the period which will elapse before the coming of infantile paralysis next year will give opportunity to

those persons in the medical profession most concerned to prepare themselves to meet the situation with all the new knowledge that the research supported by the National Foundation for Infantile Paralysis has yielded.

SANITATION OF SCHOOL LUNCHES

Increasing interest in hot lunches for school children has been stimulated by a gradual growth of interest in nutrition among children during the past two or three decades. More recently surplus commodities are being diverted to use in schools, and WPA lunch projects have been organized in several communities. The nationwide concentration on nutrition as a part of the defense effort will inevitably bring even more activity in the schools with relation to lunches.

The school lunch is especially valuable to children who live too far from school to go home for lunch or who for other reasons are compelled to carry lunches to school, and also for all others whose diet at home leaves something to be desired. At the same time the school lunch carries with it definite sanitary hazards which need to be considered and circumvented if the school lunch is to be beneficial and without danger to the health of the children.

Recognizing these facts, the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association at its last meeting authorized the preparation of a statement¹ covering sanitary requirements for school lunches. This statement is now available in mimeographed form. Single copies are provided gratis when requested on school or health department stationery. Quantities can be supplied at nominal prices, which will be quoted. Requests should be addressed to the Bureau of Health Education, American Medical Association, Chicago.

The report outlines briefly the requirements for cleanliness of the lunchroom, kitchen, utensils and dress of attendants and emphasizes personal cleanliness for attendants. There is an outline of necessary equipment for preparing food, for storing it if necessary and for proper dish washing. Pasteurized milk, or boiled milk if pasteurized milk is not available, is specified. Keeping of left-overs for use the next day is condemned and the use of day-old products, unless they contain no ingredient susceptible of spoilage or fermentation, is also interdicted. Special warnings are given with relation to products containing "cream fillings, meringues or nonacid dressings or sauces, such as mayonnaise, whipped cream and French dressings." Emphasis is placed on daily supervision by a responsible person trained for such work. Health examinations and appropriate training of personnel are specified as essentials.

¹ Sanitary Requirements for School Lunches.—A statement of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association.

HISTAMINE AND THE TOXEMIA OF PREGNANCY

Since the presentation in these columns¹ of a discussion of the presence of histidine in urine during pregnancy and its significance as a diagnostic sign, further information has accumulated. Careful study by a number of investigators has given somewhat conflicting results. The Tschopps,² who examined 600 specimens of urine from 300 patients, reported that histidinuria was found in both males and females, in health and in disease. These data have been essentially confirmed by Racker,³ who however demonstrated a considerably larger quantity of histidine in the urine of pregnancy than in normal urine. Langley⁴ concluded that, while the estimation of histidine in the urine cannot be recommended as a reliable test for pregnancy, it may be a valuable aid in the rapid diagnosis of, or routine testing for, pregnancy. Again, Racker⁵ has recently demonstrated that the amounts of histidine which can be isolated from such urine agree with the colorimetric estimations. While excretion of histidine is usually augmented in pregnancy, this result cannot be relied on as the sole diagnostic of this condition.

Kapeller-Adler has now reported further interesting implications of histidine metabolism in pregnancy and presents suggestive relationships of a metabolic product derived from histidine, namely histamine, to the toxemia of pregnancy. This pharmacologically potent base is known to arise normally from histidine in the large intestine; whether the histamine normally present in the various organs of the body has this origin or is actually formed in the various tissues is debatable. Werle and Krautzun⁶ have reported that animal tissues, notably kidney, do have the ability to decarboxylate histidine to histamine. In her more recent report, Kapeller-Adler⁷ has observed that, in patients with serious symptoms of preeclamptic toxemia, histidine was entirely absent from the urine or was present only in traces. The results have been so consistent that the author proposes the lack of excretion of histidine as a salient feature of profound toxemia. Moreover, improvement was always accompanied by an increase in excretion of histidine, which may be considered a favorable sign in the clinical condition.

In view of the evidence, Kapeller-Adler has investigated the possible nature of this derangement. Instead of being excreted, histidine is possibly being transformed into some other compound, probably one of pharmacologic activity. From a consideration of the chemical structure of histidine, its conversion to histamine seemed likely.

Histamine has been isolated⁸ from the urine in each of 6 cases of toxemia of pregnancy. A detectable amount of histamine could not be obtained, however, from 39 liters of normal pregnancy urine. These observations strongly suggest that the histamine isolated from urine in cases of toxemia of pregnancy was derived from histidine, which is normally excreted in the urine in considerable quantity throughout pregnancy.

Although many pharmacologic actions brought about by histamine⁹ indicate a basis for explaining the pathogenesis and course of toxemia of pregnancy, the mechanism whereby histidine is changed to histamine in eclampsia is not at present clear. The current evidence in connection with histamine and its relation to eclampsia is suggestive and warrants further carefully controlled study.

Current Comment

BLOOD DONATIONS FOR THE ARMED FORCES

Elsewhere in this issue¹ appears a report by Taylor discussing the need for and technical aspects of obtaining large quantities of blood plasma for the United States Army and Navy by the American Red Cross. It is apparent that a great expansion in facilities for collection of plasma is necessary if the required quantities are to be made promptly available. It is also noteworthy that the work already done by the Red Cross confirms previous reports that the withdrawal of 500 cc. of blood has no harmful effect on the health of properly selected donors. In view of the care with which the Red Cross has approached the problem, there should be no difficulty encountered in obtaining volunteer blood donors in sufficient numbers to satisfy all legitimate needs.

DOMESTIC WOVEN CATHETERS

Prior to 1939, woven catheters were made only in France, Italy and Germany. Now domestic products, made by American manufacturers, which are said to surpass foreign catheters in strength, durability and resistance to heat and chemicals are available. A catheter is a woven tubing, with the fabric base coated and polished to the desired size. Silk has been used as the base and natural resins and linseed oil for the coating. New machinery has been devised to speed up production, and nylon has been substituted for silk as the fabric base. American manufacturers have eliminated 70 per cent of the hand labor. Although there is apparently no price difference between domestic and foreign makes, the development of this substitute for foreign imports is particularly timely.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

EMERGENCY MEDICAL SERVICE FOR CIVILIAN DEFENSE

All emergency medical field units, whether organized primarily within or outside of hospitals, should be related to hospitals wherever possible. Their constituent subdivisions, the emergency medical squads, should alternate on periods of duty so as to be available to respond promptly day or night to the call of the district control center. During "waiting" periods, hospital or field drills should be held weekly.

The movement of medical field units will be controlled from the district control center, which will receive air raid warnings from the military establishments in the area. On the sounding of the alert, they will prepare for action but will not move until ordered by the district commander. A main control center will coordinate the activities of all district control centers of a large city or area. Smaller cities operate through a district control center; larger cities are subdivided into a number of districts, each under a district commander in control of the movement and activities of all civilian defense forces within his district. If the medical facilities of the district should prove inadequate to handle the load of the casualty stations and first aid posts or if the hospitals in or assigned to the districts are filled to capacity, assistance can be obtained by appeal to the main control center.

To coordinate these medical activities, the chief of emergency medical service is to be represented on the staff of the main and district control centers. Each control center will require the services of three medical adjutants, so that one will always be on duty. For these assignments the local chief of emergency medical service

should provide and instruct an adequate number of medical adjutants.

The medical adjutant in the District Control Center will keep informed of:

1. The location and number of emergency medical squads available in or assigned to the district.
2. The location of sites in the district designated by the chief of emergency medical service as casualty stations.
3. The location and number of hospital beds in or assigned to the district which are available to receive casualties.
4. The location and number of ambulances and other vehicles assigned to the emergency medical service of the district under a transport officer.
5. The maximum number of casualties which the staff of each hospital in or assigned to his district is capable of handling daily. During an incident he should be constantly advised of the number of casualties admitted to each hospital so as to be able to divert casualties to the less crowded institutions and avoid overloading.

The medical adjutant in the main control center will keep informed through the district control centers of the daily census of hospital beds available in all districts of the area and of the status of all emergency medical field units and of all ambulances and other vehicles available in the various districts. He must decide which unit or which hospital in another district will be called into service when the facilities of a given district are overloaded.

Constant vigilance in the exercise of these responsibilities is necessary if the Emergency Medical Service is to function rapidly and effectively in times of need.

GEORGE BAEHR, M.D., Chief Medical Officer.

A PANORAMIC SKETCH OF U. S. ARMY MEDICAL SERVICE TODAY

JOSEPH R. DARNALL, M.D.

Lieutenant Colonel, Medical Corps, U. S. Army

Washington, D. C.

The Army Medical Department is made up of a number of component corps, including the Medical Corps, Dental Corps, Veterinary Corps, Medical Administrative Corps, Sanitary Corps, Nurse Corps and a number of enlisted personnel, all under the direction of a Major General who is the Surgeon General of the Army. Medical Department soldiers comprise about 75 per cent of the total enlisted strength of the Army.

The Surgeon General is selected by the President from among the senior colonels of the Medical Corps and is appointed for a term of four years. The Medical Corps component of the Medical Department is composed exclusively of doctors of medicine who are commissioned in the various grades from First Lieutenant to Colonel, inclusive.

Assistants to the Surgeon General include three brigadier generals who are chosen from the senior officers of the Medical Corps, and one brigadier general who is chosen from the senior

officers of the Dental Corps. During the present military expansion half a dozen senior colonels of the Medical Corps have been made temporary brigadier generals.

MEDICAL SERVICE OBJECTIVES

The Medical Department exists primarily for the constructive purpose of conserving military man power and thus preserving the strength of the armed forces. In general, this is accomplished (1) by the selection, through properly conducted physical examinations, of only those men physically fit for military service; (2) by keeping such personnel in good physical condition, through the application of modern principles of preventive medicine; (3) by furnishing those who do become disabled with such aid, in the form of evacuation and hospitalization facilities, as will speedily restore them to health and fighting efficiency.

Like other branches of the Regular Army in peacetime, the Medical Department devotes as much time as is practicable to the training of its personnel for field duties. But because of the major mission of caring for the sick and injured, only a small proportion of medical personnel can be engaged in field training activities at any one time.

From the Professional Service Division, Office of the Surgeon General, War Department.
Read in the Scientific Sessions of the Second Triennial Medical Alumni Reunion, University of Michigan Medical School, Ann Arbor, Mich., Oct. 3, 1941.

During war or serious threat of hostilities, the Regular Army, supplemented by the National Guard and Officers' Reserve Corps, forms a nucleus for the development of a potentially powerful defense force. As Medical Department expansion is obliged to keep pace with the general growth of the military establishment, officers of the Regular Army Medical Corps, for the most part, must forsake their normal professional activities to take over Medical Department executive and administrative duties. The actual care of the sick and injured then falls chiefly on Reserve Officers who are called to active duty. Even so, there is much medicomilitary work of an administrative nature to be done by newly activated Reserve Officers. Therefore it is sometimes impracticable to assign Medical Reserve Officers to purely professional duties within their chosen fields of specialization. Every reasonable effort is made, however, to place individuals in positions where their training and ability may be used to best advantage.

PERSONNEL

The United States Army, which on July 1, 1939 consisted of approximately 13,000 officers, 675 nurses and 174,000 enlisted men, today has expanded nearly tenfold to include approximately 90,000 officers, 6,000 nurses and 1,480,000 enlisted men. Of this number about 14,000 are Medical Department officers and 109,000 are Medical Department soldiers. At present there are more officers on active duty in the Medical Department alone than were in all branches of the Regular Army combined in 1939. These officers include approximately 10,000 physicians in the Medical Corps, 2,300 dentists in the Dental Corps, 600 veterinarians in the Veterinary Corps, 1,000 nonprofessional officers in the Medical Administrative Corps and 200 technical officers in the Sanitary Corps.

Enlisted Medical Department recruits are sent, if practicable, to one of three Medical Department replacement training centers. These centers are located at Camp Grant near Rockford, Ill., at Camp Lee, near Petersburg, Va., and at Camp Berkeley, near Abilene, Texas. The replacement centers give new recruits thirteen weeks of intensive basic military training before they are permanently assigned to tactical units or stations.

In order that one may visualize how and where the commissioned and enlisted personnel of the Medical Department are utilized, I will describe briefly the more important installations.

THE SURGEON GENERAL'S OFFICE

The Office of the Surgeon General, War Department, in Washington, D. C., is the nerve center of the Army Medical Department. This office is under the direction of Major General James C. Magee, the Surgeon General of the Army, and at present includes a staff of approximately 100 officers, 4 nurses and 740 civilian employees.

The office is organized into twelve divisions to facilitate the performance of its diverse functions. It is in this office that Medical Department policies are formulated and administrative supervision of professional services to the sick and injured personnel of our Army is maintained. One division of this office manages all of the fiscal and supply business of the Medical Department, while another division is charged with the selection, classification and disposition of commissioned and enlisted medical personnel. The office, through its Preventive Medicine Division, exercises advisory supervision over military sanitation and control of communicable diseases in the Army.

The Surgeon General's Office coordinates the development of adequate facilities for the hospitalization of all sick and injured military personnel. Actual construction of hospitals, however, is a responsibility of the Quartermaster Corps. Vital statistics pertaining to the military establishment, monthly reviews of the health of the Army, and annual reports of the Surgeon General are prepared here.

The office administers the Army Medical Library, the largest medical library in the world. Dental, veterinary and nursing divisions of the office are charged with the administrative, professional and advisory supervision over the activities of their respective corps. Another division is concerned with Medical Department planning and training activities.

Let us now consider some other Army medical establishments. The more important ones are the military hospitals, dispensaries, medical supply depots, medical service schools and field medical installations. Some of these establishments, such as the Medical

Department service schools, general hospitals and supply depots, are under direct control of the Surgeon General. Others are under the decentralized control of one of the nine corps area commanders, each of whom has a corps area surgeon and medical assistants on his staff of technical advisers.

MILITARY HOSPITALS

Army hospitals fall into two main classes: (1) fixed and (2) mobile. The latter are intended primarily for use with the field forces in the combat zone of a theater of military operations. Army hospital bed capacity is planned so as to provide fixed hospitalization for 5 per cent of the total military population. Facilities are designed so that expansion can easily be accomplished to care for an additional 1 per cent. This may seem a high percentage, but actually it is not excessive when one realizes that sick soldiers cannot remain in barracks. Individuals with minor illnesses who would ordinarily be treated at home in civil life must, in the Army, be hospitalized. At present the fixed Army hospitals, including those under construction, provide facilities for the care of approximately 96,000 patients.

Fixed (immobile) hospitals include general and station hospitals. The Army general hospitals are capable of caring for 1 per cent of the total military population, while station hospitals are equipped to care for 4 or 5 per cent of all military personnel. Thus hospitalization is immediately available for 5 per cent of the entire Army and, when necessary, the facilities can be rapidly expanded to care for 6 per cent of the military population.

Prior to the current military expansion, the Army maintained only five general hospitals and about one hundred station hospitals within the continental limits of the United States. Now there are fourteen general hospitals with a total capacity of more than sixteen thousand beds. In addition to the facilities available in Army general hospitals, there are at present, completed or under construction, accommodations for approximately 80,000 patients dispersed in about two hundred and twenty-eight Army station hospitals. These establishments vary in size from twenty-five beds to more than two thousand beds each. Plans for further construction of station hospitals have been recommended which will bring the grand total of station and general hospital beds up to more than one hundred and twenty-five thousand. This should be sufficient for an army of 2,500,000 men.

Our vast military housing program has included erection of the aforesaid hospital facilities. Unlike the older permanent Army hospitals, practically all of the new buildings are of the cantonment type, as construction of permanent buildings was not authorized.

It may be recalled that, during the first World War, the American Red Cross assisted the Army by organizing the staffs of fifty base hospitals at certain civilian medical institutions in this country. In 1918 it was my privilege to serve overseas with an evacuation hospital on the western front in France, and later with our Army of Occupation in Germany. Although the mobile hospital to which I was assigned was not a "sponsored" unit, much praise was bestowed on those splendid hospitals that arrived in France with their staffs fully organized and ready to function.

Recognizing the value of the sponsored base hospitals of 1917-1918, the War Department has authorized the creation of similar affiliated units in many of the teaching institutions and larger hospitals in the United States. Today our so-called sponsored or affiliated units include sixty-eight general hospitals, thirty evacuation hospitals and twenty-five surgical hospitals. These units form no part of the Selective Service training program and are not yet an active part of the military establishment. They are designed to function in theaters of military operations and will be called into active service only in the event of a general mobilization.

The University of Michigan sponsored unit is General Hospital No. 298, with an organized hospital staff that can be quickly augmented and ready to serve, if need be, in any theater occupied by our field forces.

MILITARY DISPENSARIES

Although Army hospitals provide both inpatient and outpatient service, we also have outpatient establishments which are not attached to hospitals. These independent units, which are known as "dispensaries," are equipped to render outpatient service to

military personnel not requiring hospital care. Like Army hospitals, they are classified as "fixed" and "mobile."

The Medical Department maintains fixed general dispensaries in some of our large cities, where the size of the military population warrants their establishment, to provide outpatient medical service for military personnel stationed in those cities. There are also fixed station dispensaries (formerly known as infirmaries) at many Army stations to provide outpatient service. These station dispensaries are usually not established at small or compact military posts where station hospitals are provided. They are maintained only at small posts where no hospitals are in operation or at very large posts where, although there are station hospitals, separate outpatient services are desirable. Decentralized dental clinics each equipped with fifteen or twenty-five dental chairs and operating under the remote control of the hospital commander, are also maintained at large stations, especially where troops are scattered in widely separated areas over a large reservation.

Mobile, or unit, dispensaries are provided to serve the non-hospital medical needs of troops in the field. In the combat zone during war or during field maneuvers these mobile or unit dispensaries are called aid stations.

MEDICAL SUPPLIES

The Army Medical Department is charged, among other responsibilities, with the procurement, storage and distribution of all medical supplies used by the Army. This entails an organization of specially trained medical officer personnel, who receive practical instruction in the Army medical supply depots, which are strategically located throughout the country. Medical officers who specialize in supply work are also trained in the Finance and Supply Division of the Surgeon General's Office and are given a course of instruction at the Army Industrial College.

Medical supplies fall into two broad classes; namely, (1) those items which are employed in the routine care of the sick and injured and (2) those items used by tactical units and known as field equipment. The first broad class of medical supplies includes matériel commonly utilized in civilian medical practice. Ordinarily these items may be obtained commercially without difficulty, and their rate of consumption varies more or less uniformly with the size of the Army. Field equipment, on the contrary, is largely noncommercial, more difficult to obtain, and the rate of consumption of its different items varies from a negligible amount in time of peace to the enormous quantities which may be expended during "all out" major hostilities. Field medical equipment includes principally those items and assemblies which are peculiarly adapted for emergency medical service and evacuation of battle casualties in a theater of military operations, particularly in the combat zone.

The Medical Department at present maintains seven active supply depots in the continental United States. These depots are located at New York, Chicago, St. Louis, San Francisco, Savannah, San Antonio and Seattle. Three reserve medical supply depots are also organized and held in readiness but are inactive. Four depots are maintained outside the continental United States in Panama, Puerto Rico, Hawaii and the Philippines. More than 4,000,000 square feet of storage space is utilized in properly assembling, storing and distributing the medical supplies for our present Army of approximately 1,570,000 officers and men.

MEDICAL DEPARTMENT SERVICE SCHOOLS

Facilities for special instruction and training are available at a number of Medical Department establishments. One of the heaviest training loads falls on the Army Medical Center in Washington, D. C., which includes the Walter Reed General Hospital, Army Medical School, Dental School, Veterinary School, Army School for Dietitians and a school for physical therapy aides.

The Army Medical School normally conducts a four months course in postgraduate work for Regular Army medical officers. This course, lasting from September through December, places emphasis on practical laboratory work, preventive medicine and professional medical problems peculiar to military service. Special one month intensive courses in tropical medicine are now being held at the Army Medical School. This instruction trains about thirty medical officers each month in the essentials of

tropical medicine. The school also gives special courses for enlisted laboratory and x-ray technicians, engages in medical research concerning problems relating to the military service, and manufactures certain biologic preparations, including all the typhoid vaccine used by the Army, Navy, Public Health Service and Civilian Conservation Corps. The Veterans' Administration, Indian Service and many other agencies are likewise supplied with vaccine from this laboratory, which manufactured 33,500,000 cc. of typhoid vaccine last year.

The Medical Department also maintains a Medical Field Service School at Carlisle Barracks, Pa. This institution is equipped to teach medical military tactics and administration, which otherwise might be learned, perhaps painfully, only in the school of experience.

According to Army Regulations, the objects of the Medical Field Service School are:

1. To instruct and train Medical Department officers in the principles and methods of medical field service so as to increase their ability as instructors and to enhance their proficiency in the performance of their command and staff duties.
2. To instruct and train selected enlisted men of the Medical Department in the duties of noncommissioned officers pertaining to the organization, mobilization, training and operation of Medical Department units.
3. To act as an agency of the Surgeon General in the development and perfection of the principles and methods of field medical service.
4. To assist in the development of field sanitary equipment; to aid in the preparation and revision of Medical Department Training Regulations, instruction manuals and other publications; to make research in matters pertaining to the field duties of the Medical Department, and to disseminate to the military service information concerning the instruction and training used and developed at the Medical Field Service School.

The various courses of instruction at Carlisle parallel or dovetail one another so that the entire year is devoted to intensive teaching and training programs in which emphasis is placed on exemplary and applicatory methods of instruction. One of the important courses normally scheduled was a five months basic course for junior or newly commissioned officers of the Regular Army Medical Department. This basic course has been temporarily discontinued during the present emergency. The six weeks National Guard and Reserve Officers' course and the advanced course for Colonels, Lieutenant Colonels and Senior Majors of the Medical Department have also been discontinued for the present.

In addition to these regular courses at the Medical Field Service School, unit training camps and basic training camps were held throughout the summers prior to the present emergency to afford successive increments of Reserve Officers two weeks of field training.

Two eight week courses are now conducted annually, one beginning in September and the other in April, for the purpose of giving advanced instruction to selected noncommissioned officers of the Medical Department.

Each summer an R. O. T. C. camp is held at Carlisle, lasting six weeks. The practical field training afforded at these camps supplements the didactic instruction given during the academic year by officers at the medical school maintaining R. O. T. C. units. Similar medical R. O. T. C. camps are held each summer at several other military stations.

Because of the national emergency, the normal schedule of courses at the Medical Field Service School has been modified to meet the requirements for speed and mass production. Accordingly, short courses lasting a month were established in 1940. These are known as "refresher courses," and recently they have been lengthened to two months. These short courses, repeated every two months for new increments of officers, review the fundamentals of field medical service and furnish information concerning recent changes and advances in administration, organization, tactics and field equipment. Refresher courses are provided for Medical Department officers of all components of the Army, including Regular Army, National Guard and Reserve Corps. About five hundred officers at a time have received the benefit of these refresher courses in tactical training at Carlisle. Another three hundred officers per month have received refresher courses in hospital administration and

medical specialties at Army hospitals. The latter training includes forty exemplary and applicable courses in six different general hospitals. This instruction is aimed at familiarizing selected medical officers with the administrative routine of various military hospital staff positions, including commanding officer, executive officer, adjutant, registrar, mess officer, chiefs of services, section chiefs, ward officers and other hospital staff duties.

On July 1, 1941 an officer candidate school was established at Carlisle Barracks to train selected enlisted candidates for commission in the Medical Administrative Corps. The courses at this school last approximately three months and accommodate as many as two hundred and fifty students in each class.

Monthly courses in field sanitation are given at Carlisle to train enlisted sanitary technicians. Approximately one hundred enlisted men receive this instruction each month.

Nearly one thousand five hundred enlisted technicians are being trained each month in Army hospitals. This training is made available at six of the larger permanent Army hospitals. These enlisted student technicians receive special instruction in the work to which they will be assigned. The courses are intended to qualify selected enlisted men for assignment as technicians in x-ray, pharmacy, laboratory, veterinary, dental, medical and surgical services.

Twenty-four replacement training centers have been set up at twenty-one camps in various parts of the country. Newly inducted and volunteer recruits may be sent to these centers to receive basic military and tactical instruction in various branches of the service. Medical recruits, for example, are sent to one of three replacement centers, where they receive elementary individual training and at the same time are given instruction concerning Medical Department field units and installations.

I have stated that medical replacement centers have been established at Camp Lee, Va., Camp Grant, Ill., and Camp Berkeley, Texas. Medical Department soldiers who are not sent to one of these centers for the usual thirteen weeks of basic training receive equivalent elementary military instruction and training with the organizations to which they are assigned.

FIELD MEDICAL SERVICE

Time will not permit a discussion of medical field service organization or a comprehensive description of the more important Medical Department units that are designed to function in a theater of military operations. Briefly, these installations include, from front to rear:

Battalion and regimental aid stations to give prompt emergency treatment on the field of battle.

Collecting companies to carry the wounded from battalion areas to field hospitals, which are now known as "clearing stations."

Clearing stations (formerly called "field hospitals"), which provide necessary emergency surgical care, prepare casualties for further evacuation to the rear and return to duty those patients who are trivially wounded and not incapacitated.

Mobile surgical hospitals, which operate independently, adjacent to clearing stations, to care for extremely urgent cases and nontransportable wounded.

Evacuation hospitals, which are mobile and yet provide facilities for skilful surgical treatment of battle casualties in the combat zone.

Convalescent hospitals, near the front, where slightly wounded and sick may be detained with a view to their early return to combat units.

Convalescent camps behind the combat zone, to which rear area hospitals may send convalescing patients.

Medical supply depots in the theater of operations to receive, store and issue medical supplies and equipment for the field forces.

Field laboratories to render clinical and epidemiologic laboratory service.

Hospital trains and airplane ambulances to accomplish transfer and evacuation of patients behind the combat zone.

Station and general hospitals in theaters of operations to furnish definitive treatment and hospitalization behind the combat zone.

Each mobile surgical hospital contains, in addition to shelter, one mobile surgical unit, which possesses sufficient integral transport for its own movement, together with the necessary facilities for messing, supply and technical operation. There are two types of mobile surgical units, each with identical personnel and functions. One type moves its personnel and equipment by ordinary truck. The other type has four operating rooms, installed in a like number of bus or van type motor vehicles, in which the unit performs its technical functions.

During a great battle, such as the Meuse-Argonne in the first World War, the Medical Department may have under its immediate control more than one fourth of all the military personnel of a field force. For example, about 15 per cent of the force may become casualties, while more than 10 per cent of the force may be medical personnel required to care for the casualties, all under Medical Department control.

I have said nothing of our Army medical organization in the Philippines, Hawaii, Panama, Puerto Rico, Alaska or in the recently acquired military bases at Newfoundland, Iceland, Bermuda, Jamaica, Trinidad, British Guiana and elsewhere. Service beyond the continental limits of the United States is loosely referred to as "foreign service." Army medical men seldom dislike such assignments. Foreign service, despite its hardships, may be alluring in many ways. Furthermore, foreign service reveals to the medical officer many fascinating vistas for scientific research.

Beneath tropical skies and towering coconut palms at some of our Army outposts, medical men in uniform carry on a relentless battle against disease. Amid exotic surroundings, among strange peoples, on the fringes of deadly swamps and jungles, Army doctors are afforded professional opportunities which do not exist in the environments of our homeland.

Army medical service involves much more than professional attendance on the sick and injured. It is concerned with the organization, administration, supply, training, sanitation and field tactics of medical troops, as well as evacuation, professional care and proper disposition of military patients, at home and abroad.

Whatever may be his professional aptitude or accomplishments, the physician who seeks a career in the Army must ultimately embrace the entrancing subject of military medicine. He may do so eagerly and with devotion or he may be obliged to accept, reluctantly, the military responsibilities which are inevitable in such a career. It is on the trained medical officer that new doctors in uniform must lean heavily for advice and guidance in times of great national emergency. And it is on these new doctors, drawn into the Army from civil life, that the trained medical officer must rely for cooperation, common sense, sacrifice and professional skill.

Teamwork is a strong bulwark against inefficiency. The Medical Department, both in the zone of the interior and in the theater of operations, is one of the most important cogs in our military machine and indispensable to national defense. But it is only a part of the team. During the perilous times which lie ahead, I urge those of you who may serve in the Medical Department of the Army to cultivate the twin virtues patience and tolerance. Try to understand and cooperate with the military system. Its necessary complexities are often misunderstood, and at times misrepresented as gross inefficiency, especially by inexperienced critics. After all, it is our cherished democratic system which necessitates most of the red tape, delay and seemingly wasted motion. There is generally a good but perhaps obscure or incomprehensible reason for every action or inaction which so often irks the newcomer in the Army.

Medicomilitary enthusiasts, imbued more with tactical considerations than with tact, have in times past overstepped the bounds of common sense by admonishing the newly commissioned Army doctor, when he is assigned to field service, to forget that he is a doctor and to remember only his purely military problems. Such council, of course, can serve no useful purpose and is properly resented by medical men.

In closing, I would advise the physician who dons the Army uniform never to forget that he is a Doctor of Medicine. But he should recognize the fact that efficient military medical service often demands stern and perhaps heroic adherence to the doctrine of "the greatest good for the greatest number."

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 4853 has been reported to the Senate, proposing to authorize the hospitalization of retired officers and enlisted men who are war veterans on a parity with other war veterans. H. R. 4905 has been reported to the Senate, proposing to facilitate standardization and uniformity of procedure relating to the determination of service connection of injuries or diseases alleged to have been incurred in or aggravated by active service in a war, campaign or expedition. H. R. 6135 was reported to the House with recommendation that it pass, proposing to authorize an additional appropriation of \$150,000,000 to construct community facilities in defense areas, including hospitals, health centers and clinics. Subsequently the authorization for the additional appropriation contemplated by this bill was included in another pending bill, H. R. 6128, and that bill has passed the House.

Bills Introduced.—S. 2105, introduced by Senator Clark, Missouri, and H. R. 6196, introduced by Representative Bland, Virginia, propose that it shall be unlawful for any person to produce, manufacture, compound, possess, sell, give away, deal in, dispense, administer or transport marihuana in the Canal Zone except under a license issued by the governor of the Panama Canal. The governor will be authorized to issue any licenses necessary to permit such uses of marihuana as are related to its administration to patients by physicians, dentists, veterinary surgeons and other practitioners or to research, instruction or

analysis. H. R. 5906, introduced by Representative Barden, North Carolina, proposes to authorize annually an additional appropriation of \$5,000,000 to be allotted to the several states to provide for the promotion of vocational rehabilitation of persons disabled in industry or otherwise. The term "physically disabled persons" is defined to mean any person who by reason of a physical defect or infirmity, whether congenital or acquired by accident, injury or disease is, or may be expected to be, totally or partially incapacitated for remunerative occupation. The term "vocational rehabilitation" is defined to mean the rendering of any services necessary to the fitting of a physically disabled person for a remunerative occupation. H. R. 6116, introduced by Representative Van Zant, Pennsylvania, proposes to authorize the Administrator of Veterans' Affairs to insert a provision in all national service life insurance contracts granting the insured protection against permanent total disability occurring while his contract of insurance is in force. H. R. 6216, introduced by Representative Downs, Connecticut, proposes to extend the federal old age and survivors' insurance benefits provisions of the Social Security Act to include hospital employees, beginning July 1, 1942.

DISTRICT OF COLUMBIA

Change in Status.—H. R. 5694 has passed the House and Senate, proposing to prevent the sale of unwholesome food in the District of Columbia.

MEDICAL ECONOMIC ABSTRACTS

BRITISH COLUMBIA PREPAYMENT PLAN

The British Columbia Medical Association has organized a prepayment plan which became effective Nov. 1, 1940.¹

The Medical Service Association is incorporated under the "Societies Act" and brings together along industrial lines those interested in medical care by prepayment—employees, employers and doctors. There are three classes of members—employee members, employer members and professional members. The employee members elect two directors, employer members and professional members each elect one director. This representative board of directors is elected by the membership at large and serves without pay. The Medical Service Association is a nonprofit service organization and all dues collected are used or held for providing services to its beneficiary members and their dependents. Not more than 10 per cent of the dues may be used for administrative expenses.

Medical and surgical care includes services rendered by any doctor of medicine in the province in the home, the doctor's

office or the hospital, consultations, special medical services, such as x-ray, diagnostic aids, and laboratory examinations and the services of specialists. Thirty-five dollars is paid the doctor for obstetric services when the mother has been enrolled for ten months, including antepartum, confinement and postpartum care.

A fundamental principle adhered to in the development of the Medical Service Association has been that the paper work to be required of physicians should be kept at a minimum.

Payments are made to the doctors, not to the subscriber, and are at the rate of 75 per cent of the schedule of minimum fees of the College of Physicians and Surgeons.

For the period of operation the estimates of costs have been adequate to discharge the obligations of the Medical Service Association for medical, surgical and hospital care and to set aside a reserve for contingencies of 12 per cent of the dues.

The Medical Service Association now has nine hundred subscribers. The service has had to meet competition of contract practice and plans with salaried doctors, many of which are on a financial basis equivalent to poor relief costs. Negotiations are going on with hospital service plans to arrange for some type of cooperation.

¹ MacEwen, S. Cameron: Medical Economics, address at the Session on Medical Economics, Annual Meeting of the British Columbia Medical Association, Sept. 16, 1941, Bull. Vancouver M. A. 17:1 (Oct.) 1941.

WOMAN'S AUXILIARY

Arkansas

The auxiliary to the Bowie and Miller Counties Medical Society met for the first meeting of the current season at the home of Mrs. N. B. Daniel, September 26. Mrs. Calvin Churchill of Batesville, president of the state auxiliary and guest of honor, talked on health education, *Hygia*, health legislation and student loan funds.

The public relations meeting, October 24, was in the form of a "Nutrition Forum." The Washington County auxiliary met September 2. Seven subscriptions for *Hygia* were provided to county schools as a gift from the auxiliary.

West Virginia

The Woman's Auxiliary to the Academy of Medicine of Parkersburg opened their fall program at a joint meeting with the state auxiliary's executive board, October 8. The hostesses for the afternoon were Mrs. B. O. Robinson, Mrs. R. H. Wharton, Mrs. Athey Lutz and Mrs. A. C. Wooster. The local president introduced Mrs. Welch England. Mrs. V. E. Holcombe, formerly president of the national auxiliary, introduced Mrs. R. E. Mosiman of Seattle, president of the national auxiliary and guest speaker, whose subject was "Problems in Health Defense in Connection with Our National Defense Program."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Annual Registration Due January 1.—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licensee who does not renew his license as required is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licensee who fails to renew his license for three successive years.

ARKANSAS

Annual Registration Due on or Before January 1.—All licensees of the State Medical Board of the Arkansas Medical Society are required by law to register with the board on or before January 1 and at that time to pay such fee as has been set by the board. If a licensee fails to pay the required annual fee before March 1 of any year his license to practice automatically expires but may be reinstated on the payment of all delinquent fees and a penalty of \$1 for each year, or part thereof, of delinquency.

CALIFORNIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license, and thereafter a license may be reissued only after application and the payment of a \$10 penalty. The required fee, however, is waived with respect to licensees serving in the armed forces of the United States or in the United States Public Health Service.

Chiropractor Lovaas Convicted of Practicing Surgery.—A. M. Lovaas, a Santa Ana chiropractor, was recently convicted in the Santa Ana justice court on three counts of violating the laws regulating the practice of medicine in that he attempted to remove the tonsils of a patient by electrocoagulation. The court said that this procedure constituted the practice of surgery and that the license that Lovaas held did not entitle him to engage in such practice. A fine of \$250 was imposed on the first count and a jail sentence of thirty days on each of the remaining counts, the latter penalties being suspended during a probationary period. This case, it is reported, represents the first instance in which a California court has determined whether the removal of tonsils by electrocoagulation constitutes the practice of surgery.

CONNECTICUT

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January with the state department of health and at that time to pay a fee of \$2. Licensees who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

FLORIDA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1 with the secretary of the state board of health and at that time to pay a fee of \$1. A licensee failing to register annually is liable to a fine of not more than \$50.

ILLINOIS

Personal.—Dr. Raymond H. Runde, Mount Vernon, Mo., has been named medical director and superintendent of the Peoria County Tuberculosis Sanatorium district, with offices in Peoria, succeeding Dr. David F. Loewen, Decatur, who has

held the position for three years. Dr. Loewen will occupy a similar position at the Macon County Tuberculosis Sanatorium district.

Conference on Public Health.—The annual Illinois Conference on Public Health was held in Springfield on December 4-5 with Dr. Roland R. Cross, state director of public health, as chairman. Among the speakers were:

Dr. Anton J. Carlson, Frank P. Hixon distinguished service professor emeritus of physiology, University of Chicago School of Medicine, Are Our Present Conceptions of Health and Disease Adequate?
Dr. Clarence D. Selby, Detroit, Industrial Hygiene in National Defense.
Dr. Clifford J. Barborka, Chicago, Nutritional Deficiencies and Public Health.
Henry T. Dean, D.D.S., dental surgeon, U. S. Public Health Service, Washington, D. C., Psychiatry and Public Health.
Dr. LeRoy M. Polvogt, Baltimore, Study of Impairment of Hearing in Children.

Chicago

Society News.—The Chicago Society of Internal Medicine was addressed, December 15, among others, by Drs. Paul H. Wosika, Frederic T. Jung and Chauncey C. Maher on "Does Urologic Hypertension Exist?" and Willard O. Thompson, Norris J. Heckel and Richard P. Morris, "Production of Skeletal and Somatic Aging in Young Boys with Chorionic Gonadotropin."—Dr. Jarrell Penn, Knoxville, Tenn., discussed "Treatment of Subtrochanteric Fractures of the Femur" before the Chicago Orthopaedic Society December 12 and Dr. Walter R. Fischer, "Management of the Food: An Orthopedic Responsibility."—The Illinois Psychiatric Society was addressed December 4 by Drs. Paul T. Cash, Omaha, on "Combined Curare-Electric Shock Therapy" and Ernest Lewy, Topeka, Kan., "Some Aspects of Compensation and War Neuroses."

IOWA

Personal.—Dr. Arthur Steindler, professor and head of orthopedic surgery, State University of Iowa College of Medicine, Iowa City, recently delivered twenty lectures in Spanish on orthopedic subjects and held several clinics in Mexico, under the auspices of the National University of Mexico, Mexico City.

Institute on Industrial Health.—A special institute on industrial health was conducted at Davenport, December 2, by the Iowa State Department of Health in cooperation with the speakers' bureau and the committee on industrial health of the Iowa State Medical Society for the practicing physician, the industrial physician and the industrial manager. Speakers included:

Dr. Clarence O. Sappington, Chicago, Medical Aspects of Industrial Hygiene; Medico-Legal Phases of Occupational Diseases.
Paul J. Houser, M.S., Des Moines, industrial hygiene engineer of the state department of health, Industrial Hygiene Methods.
Dr. Carey P. McCord, Detroit, Occupational Disease in Iowa; Organization and Costs of Medical Services in Industry.
Dr. Regnar M. Sorensen, Des Moines, Venereal Disease in Industry.
Dr. Philip H. Kreuscher, Chicago, Management of Industrial Injuries.
Dr. Eugene C. Wagner, Des Moines, Human Serum (pooled) in Shock and Hemorrhage.
Drs. Arthur Steindler and Frank E. Thornton, Iowa City, Low Back Pain: Diagnosis Before Treatment.
A. D. Matheson, Davenport, The Industrialist's Viewpoint.

The day's session concluded with a panel discussion participated in by these speakers and Dr. Walter L. Bierring, Des Moines, state health commissioner, and Dr. Howard A. Weis, Davenport, president of the Scott County Medical Society.

LOUISIANA

New Medical Officer at Veterans' Hospital.—Dr. Edward O. Sage, chief of the outpatient department at the Veterans' Administration Facility in Dearborn, Mich., has been made chief medical officer of the Veterans' Hospital, New Orleans, in charge of the entire Louisiana district. Dr. Sage had been with the Dearborn facility since 1922.

Personal.—Dr. Joseph C. Menendez, New Orleans, was recently appointed director of civilian defense in the Fourth Corps Area.—Dr. Mary Elizabeth Bass, New Orleans, was recently guest of honor at a banquet given by the local branch of the American Medical Women's Association. Dr. Bass was presented with a hand printed book containing the history of the local branch.

Society News.—The Orleans Parish Medical Society devoted its meeting, November 10, to a symposium on military medicine with the following speakers: Major Frank P. Rizzo, state medical officer, Louisiana Selective Service System, New Orleans; Lieut. Col. Samuel Charles Woldenberg, chief of surgical service, LaGarde General Hospital, New Orleans; Leo J. Schoeny, D.D.S., and Lieut. Comdr. James E. Fulghum, U. S. N. R., on duty with Naval Aviation Cadet Selection Board, New Orleans.

Annual Renewal Due January 1.—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

MARYLAND

New Director of Tuberculosis.—Dr. Miriam E. Brailey, associate in epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, has been appointed director of the bureau of tuberculosis of the city health department. Dr. Brailey graduated at Johns Hopkins University School of Medicine in 1930 and received the degree in public health the following year. In 1932 she became director of the outpatient clinic for tuberculous children in the Harriet Lane Home and joined the faculty of the school of hygiene and public health.

MICHIGAN

Wayne County Society Now Owns Its Home.—The Whitney Realty Company has presented the headquarters of the Wayne County Medical Society, 4421 Woodward Avenue, Detroit, to the society. The trustees and council of the society accepted the gift, and the membership unanimously voted its approval at a meeting on December 2. The house, which has been the society's headquarters rent free for ten years, will be known as "The David Whitney House." It was built by Mr. David Whitney, contains fifty rooms, and is famous for its carved wood and parquet floors, stained glass windows and twenty fire places. *Detroit Medical News*, the society's bulletin, carried special tributes in its December 8 issue to the Whitney Realty Company in appreciation of this magnanimous gift.

MINNESOTA

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January with the secretary of the board of medical examiners and at that time to pay a fee of \$2. A licensee who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

NEW JERSEY

Organize to Promote Moral and Physical Health.—A group of ministers and physicians met in West Orange on December 4 to discuss the organization of a clinic to promote the moral, spiritual and physical health of their community. The session was under the chairmanship of Rev. Dr. John A. MacSporran, president emeritus of the Hillside Presbyterian Church of Orange and extension secretary of the Committee on Religion and Health of the Federal Council of the Churches of Christ in America, cooperating with Drs. James S. Plant, director of the Juvenile Court of Newark, Theodore R. Ford, East Orange, and Briscoe B. Ranson Jr., East Orange. Definite plans were to be made at the meeting to hold a series of seminars in January at which the working organization was to be set up, newspapers reported. It is believed that the plan will assist the physician in teaching the minister to recognize symptoms of mental maladjustment and aid the minister in contributing to the physician's understanding of the situations that lead to mental disturbance and their frequent basis in spiritual sterility.

NEW YORK

Foods for Freedom Parade.—The nutrition defense committee of Rochester and Monroe County sponsored a foods for freedom parade in the Civics Exhibit Building, November 15-19. About sixty exhibits showed the composition of the human body, its needs and how these needs are met by different foods. In the evening the program included music by school orchestras and a lecture on nutrition. Health movies were shown continuously afternoon and evening.

Annual Registration Due January 1.—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives to receive and transmit to him such

applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

Civilian Defense Program to Safeguard Water Supplies.—The statewide civilian defense plan to prepare New York state municipalities for maintaining effective and safe water service under any emergencies started on October 31, when zone water supply coordinators and assistant coordinators from all sections of the state met in the state office building, Albany. The state has been divided into twenty-three water service zones, nineteen of which are coterminous with the nineteen state health districts. The other four comprise New York City and Nassau, Suffolk and Westchester counties. Earl Devendorf, assistant director of the division of sanitation, state department of health, has been named state water supply coordinator. The deputy commissioner of health and sanitary engineer of the New York City Department of Health, county sanitary engineers of the departments of health of Westchester, Suffolk and Nassau counties and the nineteen district sanitary engineers of the state department of health have been made assistant coordinators. Water supply coordinators will determine which municipalities and industries should have their water supplies interconnected and work with local water officials in effecting the interconnections.

Conference on Chemotherapy.—The New York State Department of Health and the state medical society sponsored a conference on chemotherapy in Albany, October 7-8, with the following speakers:

- Dr. Eli K. Marshall Jr., Baltimore, Chemistry, Absorption, Distribution, Conjugation and Excretion of Sulfonamides.
- Dr. Colin M. MacLeod, New York, Action of Sulfonamides on Bacteria in Role of Immunity in the Response to Chemotherapy.
- Dr. John K. Miller, Albany, The Approved Laboratory in New York State in Relation to Chemotherapy.
- Dr. William Barry Wood Jr., Baltimore, Modes of Administration and Preparation of Solutions.
- Dr. Maxwell Finland, Boston, Toxicity and Follow-Up of Patients.
- Dr. Chester S. Keefert, Boston, Clinical Use of Gramicidin and Penicillin.
- Dr. Norman H. Plummer, New York, Pneumonia.
- Dr. Cassius J. Van Slyke, Washington, D. C., Gonorrhea.
- Dr. Edwin F. Alyea, Durham, N. C., Infections of the Urinary Tract.
- Dr. John S. Lockwood, Philadelphia, Sulfonamides in Surgery—Local and General Use.
- Dr. Benjamin W. Carey, Pearl River, Use of Sulfonamides in Pediatrics.
- Dr. John H. Dingle, Boston, Treatment of Meningitis.

The conference was planned primarily in order that authoritative opinions on the best usage of these drugs would be directly accessible to a speakers' committee appointed by the state medical society. This committee will be available throughout the fall and winter to give a course on sulfanilamide, sulapyridine and related compounds to county medical societies, hospital staffs and other medical groups.

New York City

Third Harvey Lecture.—Dr. Robert F. Loeb, professor of medicine at Columbia University College of Physicians and Surgeons, delivered the third Harvey Society Lecture of the current series at the New York Academy of Medicine, December 18. His subject was "The Adrenal Cortex and Electrolyte Behavior."

Medical Service Plan for Ward Patients.—The Community Ward Service Plan, administered by the Associated Hospital Service under the direction of Dr. Sigismund S. Goldwater, was to start operating November 1, according to the *New York Times*. It is intended to provide hospital ward service and medical care on a contributory basis to persons with limited incomes, who would ordinarily be eligible for admission to the ward service of participating hospitals. Those eligible are employed single persons with incomes of \$1,200 a year or less, husband and wife with income of no more than \$1,680 a year, and families, including children, with incomes of no more than \$2,100 a year. Enrolment is permitted only on a group basis and premiums will be collected through payroll deductions. The subscription charges for the combined medical and hospital services are \$12 a year for individual subscribers and \$27 annually for families including all unmarried children under 18 years. The family subscription will provide maternity care as well as general medical services. Hospital services will include ward accommodations in participating hospitals for a period of twenty-one days, except in maternity cases, in which the period is limited to ten days. Services will include, in addition to bed and board and prescribed diets, general nursing care, operating room, delivery room, dressings, medications, drugs, anesthesia, physical therapy, cardiographic, cystoscopic, x-ray and laboratory examinations and all other essential services. At present the area covered

by the plan includes the five boroughs of New York City, Westchester, Nassau and Suffolk counties in Long Island, and Putnam, Dutchess, Columbia, Ulster, Orange, Rockland, Sullivan, Delaware and Greene counties adjacent to New York City.

NORTH DAKOTA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1 with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$5, if a resident of North Dakota, or \$2, if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and \$0.50 for each month of default.

OHIO

Monument Honors Memory of Physician.—The Logan County Medical Society, the Logan County Historical Society and the American Legion participated in the dedication near Middleburg recently of a granite monument to the memory of Dr. Phoebe Hames Sharp, who was the first physician to practice in Logan County. According to the *Ohio State Medical Journal* Dr. Sharp, who came to Logan County with her parents in 1801, was also the founder of the first school and the first church (Friends) in that section of the state. The monument is erected near the place of her burial. As part of the dedication ceremonies Dr. Lee E. Traul, Middleburg, representing the county medical society, related the progress of the medical profession in the county.

PENNSYLVANIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

Health Institute.—The second Pennsylvania Health Institute will be held at the Penn Harris Hotel, Harrisburg, January 14-16, under the auspices of the state department of health and cooperating health agencies. Included among the speakers will be:

- Dr. Benjamin F. Jones, Bethesda, Md., Fatigue as a Problem of Industrial Health
- Dr. Frank G. Boudreau, New York, Nutrition as a Problem of Industrial Health
- Dr. James G. Townsend, Bethesda, Md., Industrial Health at the Stutes' Level.
- Dr. C. Charles Burlingame, Hartford, Conn., Relation of the Public to Mental Health.
- Dr. Hubley R. Owen, Philadelphia, Aim of Local Health Administration in Preventive Medicine.
- Dr. Wilson C. Williams, Nashville, Tenn., Relationship of the State in Local Health Work.
- Dr. Robert B. Osgood, Boston, Public Health Aspects of Chronic Rheumatism.
- Dr. Elliott P. Joslin, Boston, What Is the Place of Diabetes in a Public Health Program?
- Ira Hiscock, C.P.H., New Haven, A Coordinated Program of Health Education for the Community.
- Lon W. Morrey, D.D.S., Chicago, Dental Health Education in the Schools.

Philadelphia

The Mutter Lecture.—Dr. Walter L. Palmer, professor of medicine, University of Chicago School of Medicine, Chicago, delivered the fifty-fourth Thomas Dent Mutter Lecture before the College of Physicians of Philadelphia December 3. His subject was "The Role of Acid Gastric Juice in Gastric and Duodenal Ulceration."

National Defense Night.—The Philadelphia County Medical Society designated its December 10 meeting "National Defense Night." The following program was presented:

- Dr. Hubley R. Owen, General Activities of the Philadelphia Defense Council.
- Dr. Rufus S. Reeves, Role of the Physician in Local Disasters.
- Col. Leonard G. Rowntree, medical director, Selective Service System, Washington, D. C., Results of Examination of Registrants and Their Rehabilitation.
- Dr. Edward A. Strecker, Neuropsychiatric Problems in the Military Service.
- Major General James C. Magee, surgeon general, U. S. Army, Washington, D. C., Review of Operations of the Medical Department in the Emergency.

School Health Meetings.—The American Academy of Pediatrics through its Pennsylvania committees announces the success of a new method to elicit interest of parents and teachers in the health of young children. A series of panel

discussions was held in eleven selected schools in and near Philadelphia. The program also included presentations by the local school orchestra, words of introduction by well known school or other leaders and the showing of the talking movie "Bobby Goes to School." Each panel consisted of a chairman and four associate pediatricians and in some cases an educator and a nurse. Each chairman was equipped with questions received from parents or teachers in advance or preselected as suggestive questions by panel members after the panel was started. Questions were invited from the floor on child health and school health problems. The meetings were timely because they were held at an early period in the school year when parents and teachers have to face a winter of possible infections and health is an important consideration. Eleven meetings in eleven schools reported an attendance of 175, 550, 500, 525, 500, 175, 125, 800, 1,000, 250 and 400, making a total of 5,000 consisting mostly of parents, teachers, doctors, social workers and nurses who attended these "Going to School Health Meetings." Plans are now being considered for a follow-up program to rivet the value of these meetings.

Pittsburgh

Mellon Institute Chemist Receives Remington Medal.—George D. Beal, Ph.D., assistant director of the Mellon Institute for Industrial Research since 1926, was awarded the Remington Medal of the American Pharmaceutical Association for 1941 at a dinner given by the New York branch at the Hotel Pennsylvania on December 4. Dr. Beal received the degree of doctor of pharmacy at Scio College, Scio, Ohio, in 1907 and doctor of philosophy at Columbia University, New York, in 1911. From 1911 to 1926 he was on the faculty of the University of Illinois, Urbana, becoming professor of analytic and food chemistry in 1924. He is a member of the Committee of Revision of the U. S. Pharmacopeia. In 1937 Dr. Beal was president of the American Pharmaceutical Association and in 1920 received the Ebert Prize awarded by the association.

TEXAS

Appointment at Texas.—Dr. Carl A. Nau, formerly director of the Texas division of industrial hygiene, is now professor of physiology and preventive medicine and head of the department, University of Texas School of Medicine, Galveston, it was recently announced. Dr. Nau graduated at Rush Medical College, Chicago, in 1935.

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1 with the state board of medical examiners and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

GENERAL

New Study on Alcohol Problems.—The Research Council on Problems of Alcohol will undertake a study of basic disorders and environmental factors that cause excessive drinking and the problem of alcoholism as it might affect industrial production, according to an announcement made at its annual meeting, November 25, in New York. One of eight group sessions was devoted to this phase of alcoholism. Dr. Winifred Overholser, Washington, D. C., was reelected chairman of the council's board and Dr. I. Ogden Woodruff, New York, was elected vice chairman.

Dr. Rappleye Named President of Macy Foundation.—Dr. Willard C. Rappleye, commissioner of hospitals of the city of New York, and dean and professor of medical economics, Columbia University College of Physicians and Surgeons, has been elected president of the Josiah Macy Jr. Foundation, New York, effective January 1, to succeed the late Dr. Ludwig W. Kast. The foundation is organized to further medical education. Dr. Frank Fremont-Smith is director of the medical division. For the four years 1937-1940 a report showed cash disbursements of \$951,512 for health studies and research.

New Annual Award in Urology.—The American Urological Association announces the establishment of an annual award, not to exceed \$500, for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize will be determined on merits of the work presented, and, if the committee on scientific research of the association deems none of the work submitted worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. Essays must reach the secretary, Dr. Clyde I. Deming, 789

Howard Avenue, New Haven, on or before April 1, 1942. The American Urological Association's principal object is "to encourage the study, improve the practice, elevate the standards and advance the cause of urology."

Annual Campaign for Infantile Paralysis Funds.—January 12 will mark the official opening of the annual campaign for funds to support activities of the National Foundation for Infantile Paralysis. On January 30, designated the Diamond Jubilee Birthday Celebration, birthday balls throughout the country will observe President Roosevelt's sixtieth birthday. National and local chairmen of the National Foundation for Infantile Paralysis met in annual session in Washington, December 2, to discuss plans for the forthcoming campaign and to hear reports on the foundation's activities of the past year in various states where severe epidemics of the disease were reported. During 1939, 1940 and 1941 nearly 26,000 persons have been stricken with infantile paralysis, it was stated. A percentage of the total funds collected in the annual drive is returned to the states for local aid, the remainder being retained by the National Foundation for maintenance, grants in aid and other projects.

Bibliography of Pharmacology and Chemotherapy.—Beginning with volume 3 (1942) the name of the *Bibliography of Pharmacology* is changed to *Bibliography of Pharmacology and Chemotherapy*. No change in scope is contemplated; "Chemotherapy" is added only to make the title more accurately descriptive. The *Bibliography's* field is defined thus: "A reference list of current American and foreign literature relating to the action of known chemical compounds (natural or synthetic) on animal organisms and to therapeutic use of such compounds, including clinical investigations but not including routine clinical and case reports." Format will be modified by heading each entry with a blank line for insertion of the subscriber's own index heading, as an aid to those who mount clipped *Bibliography* items on index cards. Below this line each entry will begin with an optional index heading (in capitals) selected by the compiler. The annual subscription rate is \$3.50, or \$2.50 to members of the Friends of the Hooker Scientific Library. Requests for more information or for a specimen page may be addressed to the Hooker Scientific Library, Central College, Fayette, Mo.

Fellowships in the Medical Sciences.—Fellowships in the medical sciences, similar to those which have been administered by the Medical Fellowship Board of the National Research Council since 1922, will again be available for the year beginning July 1, 1942. These fellowships, supported by grants from the Rockefeller Foundation to the National Research Council, are designed to provide opportunities for training and experience in research in all branches of medical science. They are open to citizens of the United States or Canada who possess an M.D. or a Ph.D. degree and are intended for recent graduates who are not yet professionally established. In addition to these fellowships the Medical Fellowship Board administers two groups of research fellowships, made available through a grant from the National Foundation for Infantile Paralysis, Inc. The first group, open to applicants who hold either the Ph.D. or the M.D. degree, is to provide opportunities for special training and experience in the study of filtrable viruses. The second group, open only to graduates in medicine who have completed one or more years of hospital experience in clinical surgery and are planning a career in orthopedic surgery, will provide opportunities for training and research in those basic medical sciences which will be of value in furthering progress in the field of orthopedic surgery. Fellows will be appointed at a meeting of the Medical Fellowship Board on February 28. Applications to receive consideration at this meeting must be filed on or before January 1. Appointments may begin on any date determined by the board. For further particulars address the Secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington, D. C.

Hunt for Home and Farm Accident Causes.—The American Red Cross launched a five day "hazard hunt" on October 26 for the elimination of home accident causes, which in 1940 claimed thirty-three thousand lives, according to a release. The survey was to be conducted through the distribution of ten million "check lists," an index of hazards designed to help the householder locate and eliminate the dangers. A similar index, listing accident hazards of the farm, was to be distributed in rural sections. Teachers were provided with special material to interpret the "check lists" to enable school children to assist their parents in the "hazard hunt." The children also announced plans to sponsor accident prevention courses through the three thousand seven hundred chapters of the Red Cross, which is the first national program of its type to be undertaken by the organization. A minimum of nine

hours' instruction will be required for courses in home accident prevention and twelve hours to include farm accident prevention.

In reporting on its "hazard hunt," the Red Cross stated in addition to the thirty-three thousand deaths last year from home accidents, there were four thousand five hundred persons who died as a result of occupational mishaps on the farm. An estimated five million persons suffered home injuries involving hospitalization or treatment by a physician. Statistics provided by the National Safety Council reveal that more than half of all home accident deaths last year resulted from falls occurring on stairs, slippery floors, insecure rugs as a result of poor lighting and the use of chairs and other articles of furniture as improvised stepladders. Burns and accidental poisoning as causes of death were next in order. The mounting farm accident toll was attributed to mechanization of the American farm. Ill tempered animals was the second cause in this classification. Estimates place the number of "serious" type injuries at fifty for each farm accident death, a national total of two hundred and twenty-five thousand disabling injuries, the release stated.

CANADA

University News.—The Rockefeller Foundation has granted \$25,000 to McGill University Faculty of Medicine, Montreal, for research in endocrinology for five years under the direction of Dr. John S. L. Browne, assistant professor of medicine and pathologic chemistry, *Science* reports.

Officers of British Columbia Association.—Dr. Cecil H. Hankinson, Prince Rupert, was elected president of the British Columbia Medical Association at its recent meeting in Vancouver. Other officers are Drs. Alfred H. Spohn, Vancouver, and Philip A. C. Cousland, Victoria, vice presidents; Allen Y. McNair, Vancouver, honorary secretary-treasurer, and Morris W. Thomas, Vancouver, executive secretary. The association is the British Columbia division of the Canadian Medical Association.

New Publication on Biology.—The Société de Biologie de Montréal has announced the publication of a review which will be its official organ and which will contain also reports of research. The membership of the society includes physicians, physiologists, biochemists, pharmacologists, bacteriologists, zoologists and others. The *Revue canadienne de biologie*, which will be published in French, will appear under the auspices of the Université de Montréal. The society held its first meeting of the year recently in the laboratory of physiology at the university.

Personal.—Dr. Edmund Arnold G. Branch, Montreal, has been appointed director of the Provincial Bureau of Laboratories of New Brunswick. He succeeds Dr. Robert A. H. MacKeen, St. John, who has been named pathologist to Camp Sussex Hospital, an active service commission with the Royal Canadian Army Medical Corps. Dr. Branch has worked with the Rockefeller Institute, New York, Harvard Medical School, Boston, and McGill University Faculty of Medicine, Montreal. —Dr. Charles H. Best, professor and head of the department of physiology, and director of the Banting-Best Department of Medical Research, University of Toronto Faculty of Medicine, has been appointed honorary lieutenant-commander of the Royal Canadian Navy.

FOREIGN

Personal.—Dr. Leonard Gregory Parsons, professor of infant hygiene and the diseases of children, University of Birmingham Faculty of Medicine, Birmingham, England, who has been acting as deputy dean, has been named dean, succeeding Dr. Arthur Stanley Barnes, who resigned after serving for ten years, according to *Science*.

A Morison Shelter in His House.—A British correspondent writes on October 3: "Things are very quiet here now. We have had no air raid of any importance on London for many months. Severe damage has been done in many places, some of it irreparable in the case of historic buildings and the Museum of the Royal College of Surgeons, which I have described in my letters. But London is so vast that the damage is very small in proportion to the whole—nothing like 1 per cent I should say. We expect some trouble in the coming winter from the Luftwaffe, but not on the previous scale. For one thing they will probably be too busy elsewhere and for another they should have to pay more dearly for whatever they do. I have a Morison shelter in my house. It is an iron table guaranteed to hold up 73 tons. If the house should come down, those under the table cannot be crushed to death by the debris. I need not say we are all full of calm confidence in the future. We were that in our darkest hour when we stood alone after the collapse of France."

Medical Aspect of the Problem of High Production

All our energies are being put into our war effort with the object of the maximum of industrial production. But, being a free country, we have our critics. At a recent meeting of engineers to consider war production Mr. E. C. Gordon, chairman of the Engineering Industries Association, criticized output, stating that production in engineering industries, measured by square foot of factory space or pound weight of product per hour, has declined. To this criticism a leading physician, Dr. J. A. Ryle, professor of medicine in the University of Cambridge, has replied in the *Times*. He wonders whether it occurred to Gordon's audience to remember that other measurements besides square foot of factory space and pound weight of product per hour must be taken into account if a true assessment of causes and effects is to be reached and that the human machine, however willing, when called on to contribute "every available man hour" produces less—except over short periods of drive—than the human machine handled according to the rules which physicians, physiologists and psychologists have prescribed after careful study. Experience and experiment in times of peace and during the last war have clearly shown that during prolonged periods of pressure industrial fatigue results in falling output, and that output again increases when hours are shortened, proper rest periods are instituted and a sufficiency of holiday is allowed. After the evacuation of Dunkirk a general speed up became imperative for many months, but the rising tempo of the war has continued to demand a rising tempo of production. Long hours and overtime, the monotony of repetitive work, noise, journeys from and to the factory, private and public anxieties and rationing, not to mention patriotic zeal itself, have begun to have their anticipated effect on muscle and nerve and mind. Is sufficient attempt being made to counter these adverse forces?

The symptoms of industrial fatigue include bodily and mental weariness, poor sleep, flagging digestion or appetite, irritability or depression and a slowing up of movements and of memory. They commonly appear first in "the willing horse," that is, the more conscientious and efficient worker. These symptoms cannot be quantitatively assessed. The measurable symptom is falling output. Engineers are scientifically minded and should appreciate the contributions to knowledge made by their scientific colleagues, whose study is that of the most intricate and valuable of all machines—the human body. Professor Ryle feels sure that he would have the support of the whole medical profession in urging on the government the importance of this very vital aspect of the production problem.

Ocular Injuries in the War

At the annual congress of the Ophthalmological Society a discussion took place on the experiences of ocular injury in the war. O. M. Duthie said that ruptures had proved the most frequent of all serious injuries. Even when the injury was not severe the end results were deplorable. Many cases of rupture, especially those due to flying glass, were virtually untreatable. Subconjunctival ruptures, with or without dislocation of the lens, were not infrequent.

Solly Zuckerman restricted himself to civilian air raid casualties and dealt with injuries supposed to be due to blast. He had studied the records of the last war and found nothing to suggest that changes in the eyeball were produced by blast. At

relatively high pressures, to be experienced only close to the bomb, changes, of which the most common was retrobulbar hemorrhage, would occur, but such cases would probably end fatally in any event.

E. B. Alabaster analyzed 100 cases of eye injury admitted to a casualty hospital after air raids. Of these, 60 were cases of traumatic conjunctivitis, 21 were penetrating wounds caused by metal or glass, 6 were corneal abrasions, 5 were subconjunctival hemorrhage, 5 were injuries only to the lids and there was 1 case each of central retinal block, detached retina and orbital cellulitis. Of the 21 cases of penetrating wounds, 12 required enucleation of the eye.

Herbert Caiger said that nothing had brought home to him the horror of this war so much as the case of a man, aged 66, injured in a shelter. One eye was absent and the man declared that it had been blown right out of its socket, while the other eye showed detachment of the retina.

R. C. Davenport and others referred to the frequency with which intraocular foreign bodies were found to be nonmagnetic, in keeping with the low ferrous content of shell and bomb cases used in this war.

EYE PROTECTION IN WARFARE

Sir Richard Cruise said that at least 50 per cent of eye injuries such as ophthalmic surgeons saw in the last war could be prevented by some form of practical eye protection. As reported previously in *THE JOURNAL* (June 15, 1940, p. 2397) he has introduced a visor. It was urged against it that visibility was seriously impeded. Even if this were so, the visor need not be lowered on any occasion when it is likely to handicap the wearer. Harrison Butler pleaded for the use of an official visor not only for soldiers but for fire watchers and others engaged in civilian protection. The question was remitted to the council of the society to consider taking up with the Ministry of Home Security the issue of some form of eye protection along with the steel helmet for civilians.

Immediate Training of the Disabled

Heretofore there has been an interval after the discharge of disabled men from the hospital when they have been no one's particular care. Their medical and surgical treatment has ended before the business of restoring them to employment has begun. Mr. Bevin, minister of labor and National Service, has prepared a scheme which remedies this. No time will be lost in the training and resettlement in industry of persons disabled while on war service or in civil life. The scheme is designed to cover all disablement however caused—by wounds, industrial or other accidents or disease. It will be open to all persons over 16 who are unfitted by disablement from resuming their normal occupation as well as those who are handicapped by disablement from obtaining satisfactory employment. During the war it will be necessary to concentrate on training for occupations which are in demand in war time. From the patients themselves and from their physicians, individual requirements of employment will be ascertained, and possibly the expected employment may influence the process of rehabilitation. By making contact with a patient before completion of his hospital treatment, the Ministry of Labor will be able to interest itself in his future much earlier, and his return to employment will be made easier and quicker. Under present arrangements both men and women are already being trained in government training centers and technical colleges or with employers for various kinds of munition work. Many of these occupations are suitable for disabled persons. The new scheme puts them in the first and immediate category. Training allowances will be paid to men at the rate of \$8 and to women at the rate of \$6 a week. The juvenile rates are \$4 for boys and \$3.50 for girls. In addition, a person being trained is given a midday meal.

Ammonia and the Gas Mask

The government states that the gas mask which is issued to all civilians will protect against any gas likely to be used by the enemy. Ammonia is not in this class, and the masks are not designed for protection against it. But in an accident in an air raid which occurred a year ago it was found that some protection is afforded. The connecting pipe of an ammonia condenser was punctured by a fragment of flying metal and seventy-five persons in a crowded shelter suffered from inhaling the ammonia. Seven of them died. But no one wearing a gas mask, whether a member of a first aid party called in to help or a shelterer who had the sense to don his mask on the first experience of the acrid smell, suffered. In the pamphlet of instruction the Ministry of Home Security states that the gas masks, although not designed for the purpose, do afford some protection against ammonia. But it subsequently issued a warning on this point. Though they give some protection against the immediate danger from ammonia, when worn subsequently ammonia is liberated from the container in concentrations which may produce serious discomfort or even be dangerous. This effect occurs even when gas free air is drawn through the mask, and if it should occur in the presence of war gas the wearer is completely deprived of protection. He cannot wear the mask because of the ammonia given off as he breathes through the container and so will be exposed to the war gas. The gas mask should therefore not be relied on for protection against ammonia. If in an emergency it has to be worn while escaping from an area seriously contaminated with ammonia, a fresh container should be substituted for the old one as soon as possible.

The Influence of War on Surgery

In a lecture on the influence of war on surgery Mr. Zachary Cope said that surgery had always been an art but only recently a science. Up to the time of Harvey's discovery of the circulation of the blood it was a crude art, and for the most part surgeons learned their lessons on the battlefield. It was in the Franco-Prussian war of 1870 that antiseptics were given their first big trial. Modern wars were on so large a scale that they provided unparalleled opportunities for the trial of new remedies. The intensive research necessitated by the demands of war might concentrate within a year what would usually take ten years to do.

In the last great war the prevention of tetanus by specific serum was standardized and the treatment of shock and hemorrhage by blood transfusion made readily available. That war was also the chief means of putting thoracic surgery on its present sound foundation. Even more striking was the rapid and wonderful development of plastic surgery.

In the Spanish civil war the main advance was the discovery by Trueta that wounds treated by excision and encasement in plaster healed better than those treated by splinting and daily dressing. The present war had already provided important contributions to surgery. The work of Colebrook on the local anti-septic action of the sulfonamides and the experimental results of Zuckerman's researches on the effect of blast were noteworthy.

The Nutrition Society

The people of Britain have not allowed the war to prevent progress in many directions. Of this the latest example is the foundation of the Nutrition Society. Before the war the need for such a society was often discussed by workers on nutritional research, and a year ago informal meetings of about twenty representatives of the principal laboratories began. A provisional committee consisting of representatives of hospital schools, schools of agriculture and nutrition research laboratories, with Sir John Orr, F.R.S., as chairman, has been formed. About two hundred and thirty scientists who have been working on nutrition have been invited to become original members.

Of these about fifty are medical men and women. During the war the society will hold meetings at various research institutes. The first meeting has been held at Cambridge and was opened by an introductory address by Sir Gowland Hopkins, F.R.S. Louis Harris, A. M. Sinclair, John Yudkin and G. W. Robertson discussed "Assessment of the Level of Nutrition in Man"; B. S. Platt, R. H. Dobbs and W. C. W. Nixon, "Clinical Signs of Dietary Deficiency"; C. K. Crowther, H. H. Green and John Hammond, F.R.S., vice chairman of the society, "Nutrition of Farm Animals." An open discussion followed. The new society performs the valuable service of bringing into touch with one another workers in various fields. It has been difficult for the clinician to keep up with the advances of the biochemist or the agriculturist planning production to make full use of the knowledge of the dietitian for the community's needs. Here is the remedy.

Rose Hips as a Source of Vitamins

We are producing much more food by extending our agriculture. We are also turning attention to wild products not normally used in any quantity. Plans have been made by the Ministry of Health to harvest the vitamin wealth of our hedgerows in the form of the hips of the wild rose, which are particularly rich in vitamin C, twenty times richer than oranges. Their collection is being organized through schools, boy scouts, girl guides and women's institutes. The hips will be used to make a syrup for the benefit of adults as well as of babies and children. They will also be made into a purée, which will be converted into jam by the addition of sugar. According to a bulletin issued by the Children's Nutrition Council the purée should contain 160 to 600 mg. of ascorbic acid per hundred grams and the jam 130 to 230 mg. Thus there should be at least three 50 mg. doses of ascorbic acid in slightly over 3 ounces of jam. Half an ounce eaten daily with bread would provide a useful supplement to the vitamins obtained in the normal diet. It is interesting that rose hips are a traditional food of European peasants.

Anglo-Soviet Medical Cooperation

The formation of the Anglo-Soviet Medical Committee was reported in a previous letter. An executive committee formed to carry out the plans reports that twenty-six physicians have volunteered to help in translation from Russian. The Society for Cultural Relations with Russia has handed over all its medical literature to the committee. The task has arisen of advising lay organizations on the purchase of medical supplies for Russia. The committee will accept responsibility for giving such advice but will not be responsible for making purchases or arranging shipments. Welsh miners have raised \$300,000 for this purpose. Lord Dawson and Lord Horder suggested that the committee should work with the Red Cross in this matter. A subcommittee was appointed to explore the situation and give advice.

Reduction in Air Raid Casualties

The Ministry of Home Security announces the civilian casualties in air raids in September as 217 killed and 269 injured and detained in the hospital. A year ago the corresponding figures were 6,955 killed and 10,624 injured. For September 1941 the killed or missing numbered 87 men, 73 women, 45 persons under 16 and 12 unclassified. The number hospitalized included 129 men, 111 women and 29 persons under 16. In the first six months of 1941 18,698 persons were killed and 20,451 injured. The maximum number in one month was reached in April, when 6,131 were killed and 6,900 injured. The great reduction since that time is due mainly to a falling off in attacks from the air.

A Veteran Pediatrician

Sir Thomas Barlow, the eminent pediatrician, celebrated his ninety-sixth birthday on September 4. He is still up and about and is appreciative of the good wishes of his admirers.

RIO DE JANEIRO

(From Our Regular Correspondent)

Oct. 18, 1941.

A New Face Reflex

A new face reflex is described by Austregésilo Filho of Rio de Janeiro. It is elicited by the percussion of the cheek. When positive, there is contracture of the orbicularis of the upper lip. This contracture may be on the same side (homolateral), both sides (bilateral) or opposite side (heterolateral). It is found in emotional patients without pathologic evidences and in psychoneurotic patients, in neurasthenia. When the reflex is absent on one side in patients with increased intracranial pressure it is suggestive of a lesion on the posterior fossa. The reflex also disappears on one side in cases of symptomatic trigeminal neuralgia.

Austregésilo has studied the condition for fifteen years and his conclusions are based on the examination of 500 patients.

Vaccination Against Tuberculosis

The administration of BCG vaccine against tuberculosis is widely practiced in the large Brazilian cities; even in many towns of the interior of the country its use is increasing constantly. In Pelotas, Rio Grande do Sul, whose population is estimated around 95,000 inhabitants, 78.86 per cent of newborn infants received BCG in 1940, while the rate for 5 years ago was only 25.30 per cent. The BCG service began here in 1933, when 3.97 per cent of the children were submitted to this form of immunization. The accompanying table demonstrates how widely this method of prevention has been accepted by the people:

Infants Who Received BCG

Year	Per Cent
1933	3.97
1934	14.26
1935	18.46
1936	25.30
1937	29.71
1938	33.33
1939	60.25
1940	78.86

Arlindo de Assis of Niteroi, Rio de Janeiro, who was the pioneer of BCG vaccination in Brazil, accomplished some researches on hyperallergic tuberculin tests following peroral immunization against tuberculosis. One hundred and forty-six infants and children aged from 2 months to 14 years were tested with old tuberculin by the Pirquet and Mantoux methods. None of them reacted to 2 mg. of tuberculin in intradermal injection. Roentgenologic research proved that none had pulmonary tuberculosis. Then they were given 200 mg. of living BCG a month, fasting in the morning. After twelve months 40 children (27.38 per cent) remained nonreactors to tuberculin in spite of the BCG vaccination; 6 other children (4.10 per cent) showed doubtful results of similar Mantoux tests; but 100 (68.52 per cent) became clearly hypersensitive to tuberculin. Although the reactivity was so high, clinical and roentgenologic examinations did not demonstrate any evidence of a virulent tuberculosis complicating BCG vaccination. The gastric contents of the principal reactors were injected into guinea pigs, which failed to acquire tuberculosis. The conclusion reached by Arlindo de Assis was that all changes occurring in the primarily nonreacting children, from the point of view of tuberculin hypersensitiveness, should depend on specific effects of the BCG bacilli, which would be absorbed by the gastrointestinal route. This hypersensitiveness decreases progressively.

Among factors which would have influenced such a result were (1) the high viability of the BCG vaccine as prepared in this country, (2) the comparatively high amount of BCG

bacilli introduced by mouth and (3) the fasting condition of the children at the time of their vaccination. Dr. Arlindo de Assis concludes that the oral route proved efficient. Occasional examples of specific hyperallergy caused by the oral use of BCG seem to afford definite evidence that a large amount of living bacilli can be absorbed by the gastrointestinal canal.

Intoxications with Triorthocresyl Phosphate

Dr. R. Stachelin, professor of internal medicine and director of the medical clinic in Basel, reported to the Basel Medical Society 83 cases of poisoning with triorthocresyl phosphate. He recalled that around 1900 the same type of poisoning had occurred in treating tuberculosis with creosote phosphate. During 1929, 15,000 cases became known following the drinking of adulterated Jamaica ginger. These cases concerned chiefly old persons and some drunkards. The third series of such intoxications which have become known concerned attempts at abortion with apiol. The cases under consideration here were caused by mistaking triorthocresyl phosphate for a food oil in the preparation of cheese bread. In many cases an acute gastroenteritis developed one hour after eating; in a few cases protein was detected in the urine. After a short time the patients felt well again; after a latent period of from fourteen to twenty days however, 78 of the 83 patients had muscular pains and paralysis of the motor nerves, the peripheral groups of the arms and legs being most severely involved. In the later course, fibrillar twitching in the thighs and calves, prolonged erections, profuse sweating, headaches, insomnia, loss of hair and signs of incontinence were seen occasionally. All reflexes, with the exception of the achilles tendon reflex, were intact; the musculature of the abdomen and back functioned properly. Claw hand was observed. The severity of the symptoms was not dependent on the amount of the poison. Paralysis of the peroneus resulted in the "rooster step" walk. The internal organs were free from changes, except that there was an occasional increase in diastase values. All symptoms regressed. The treatment consisted chiefly in the administration of thiamine hydrochloride. The result was always the same, even in the patients who were treated with thiamine hydrochloride and strychnine (9 mg.). None of the patients died. Microscopic examination of the nerves revealed degeneration of the myelin sheaths (lipoid solubility); degeneration of the anterior horn was observed only in severe cases. Ophthalmologic examination disclosed that the visual disturbances, which developed in about one third of the cases, were chiefly the result of disturbances in accommodation and of the contraction of the vessels of the fundus oculi.

In the discussion that followed, it was brought out that the muscle groups which are most taxed during physical work (legs, right hand) were most severely involved in the poisoning.

Deaths

Dr. Adolpho Lutz, a descendant of an old Berne family, died in Rio de Janeiro. He was active in the field of tropical medicine and medical zoology and made special investigations on the transmission of tropical infectious diseases through insects. The Brazilian state of São Paulo recently founded in his honor the Adolpho Lutz Institute. Rio de Janeiro will found a museum of natural history which will bear his name.

Prof. Hermann Matti, appointed in 1938 as professor of surgery and director of the surgical clinic of the University of Berne, succeeding de Quervain, died aged 62 years. Matti successfully continued the illustrious tradition of Kocher and de Quervain, but in the spring of this year was obliged to retire because of ill health. Matti wrote a widely used textbook on fractures.

Deaths

William Hemphill Bell * Medical Director, Rear Admiral, United States Navy, retired, Chevy Chase, Md.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; was appointed an assistant surgeon in the navy in 1898; was advanced through the various grades of the service; retired Jan. 1, 1936 on his own application with the rank of rear admiral; was head of the division of preventive medicine in the bureau of medicine and surgery; delegate to the second session of lectures of the International Bureau of Documentation on Military Medicine, Liège, Belgium, in 1932; first editor of the *U. S. Navy Medical Bulletin*, when it was established in 1907; member of the House of Delegates of the American Medical Association in 1907; fellow of the American College of Surgeons; aged 68; died, November 11, of cerebral arteriosclerosis and hypostatic pneumonia.

Albert Wynne Harris * Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1901; associate professor of neurology at his alma mater from 1909 to 1925, associate professor of clinical neurology and psychiatry from 1925 to 1927 and since 1927 professor of clinical neurology and psychiatry; was president of the Nashville Academy of Medicine; served with the Vanderbilt unit in France during the World War; member of the Southern Psychiatric Association; aged 63; died, December 7, of heart disease.

Andrew Porter Brown, Salina, Kan.; University of Kansas School of Medicine, Kansas City, 1932; member of the Kansas Medical Society; aged 32; first lieutenant in the medical reserve corps of the U. S. Army, serving as a flight surgeon at the Air Corps Gunnery School at Panama City, Fla., where he died, November 4, of infantile paralysis.

William Fero Cannon, Fayetteville, Tenn.; University of Nashville (Tenn.) Medical Department, 1892; Vanderbilt University School of Medicine, Nashville, 1892; member of the Tennessee State Medical Association; past president of the Lincoln County Medical Society; aged 72; died in November of injuries received in a fall.

Anthony Simon Maciejewski, Newark, N. J.; Temple University School of Medicine, Philadelphia, 1916; member of the Medical Society of New Jersey; served during the World War; assistant police surgeon; on the staff of St. James Hospital; aged 55; died, November 7, of carcinoma and cirrhosis of the liver.

Franklin W. Sol Raiter, Cloquet, Minn.; Milwaukee Medical College, 1911; member of the Minnesota State Medical Association; served during the World War; part owner of a hospital bearing his name; aged 52; died, October 2, of cerebral hemorrhage and hypertensive cardiovascular disease.

Samuel L. Carson, Vincennes, Ind.; Hospital College of Medicine, Louisville, Ky., 1898; member of the Indiana State Medical Association; formerly county coroner; aged 74; died, November 10, in the Presbyterian Hospital, Denver, of hypertrophy of the prostate and auricular fibrillation.

Archibald Buchanan, Troy, N. Y.; Albany Medical College, 1895; member of the Medical Society of the State of New York; for many years county coroner; served during the World War; aged 75; died, November 16, of coronary sclerosis and generalized arteriosclerosis.

William F. Chenoweth, Nogales, Ariz.; Medical College of Ohio, Cincinnati, 1888; past president of the state board of medical examiners; member of the Arizona State Medical Association; aged 76; died, August 20, in Santa Barbara, Calif., of carcinoma of the right lung.

Maurice Joseph Lippman * New York; University and Bellevue Hospital Medical College, New York, 1907; assistant, allergy clinic, New York Post-Graduate Medical School; aged 56; died, October 31, in the Beth Israel Hospital of hemangiosarcoma with metastasis.

Benjamin Cyrus Bell, Santa Monica, Calif.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1898; fellow of the American College of Surgeons; aged 71; died, September 3, of cerebral hemorrhage, arteriosclerosis and chronic myocarditis.

George S. Henderson * Holcomb, Ill.; College of Physicians and Surgeons of Chicago, 1895; past president of the Ogle County Medical Society; aged 77; died, November 4, in the Swedish American Hospital, Rockford, of coronary thrombosis.

Arthur Paul Maloney, Fonda, Iowa; John A. Creighton Medical College, Omaha, 1910; member of the Iowa State Medical Society; past president and secretary of the Pocahontas County Medical Society; aged 59; died, October 24, of uremia.

Joseph C. Kugler, Jackson, Mich.; Medical College of Ohio, Cincinnati, 1886; member of the Michigan State Medical Society and the American College of Radiology; aged 79; died, November 23, in the W. A. Foote Memorial Hospital.

George Washington Duncan * Iberia, Mo.; Washington University School of Medicine, St. Louis, 1908; past president of the Miller County Medical Society; aged 62; died, November 3, in St. Mary's Hospital, Jefferson City, of pneumonia.

William Max Fearon * Los Angeles; College of Physicians and Surgeons, Los Angeles, 1913; served during the World War; aged 52; died, November 11, in the Methodist Hospital of Southern California of coronary thrombosis.

Arthur Clinton McKenney, Los Gatos, Calif.; College of Physicians and Surgeons of San Francisco, 1908; formerly assistant clinical professor of medicine at the Stanford University School of Medicine; aged 71; died, October 4.

John George Frederick Holston * Zanesville, Ohio; Jefferson Medical College of Philadelphia, 1903; president of the Muskingum County Academy of Medicine in 1927; aged 62; died, November 2, of myocardial degeneration.

Anton Otto Frana, Chicago; Jenner Medical College, Chicago, 1917; member of the Illinois State Medical Society; served during the World War; on the courtesy staff of the Evangelical Hospital; aged 56; died, November 18.

Wallace Longfellow Meyers, Livermore, Calif.; University of California Medical School, San Francisco, 1909; aged 60; died, August 12, in the Lane Hospital, unit of Stanford University, San Francisco, of nontropical sprue.

Eli George Davis, Lewistown, Ill.; Kentucky School of Medicine, Louisville, 1881; member of the Illinois State Medical Society; aged 88; died, November 11, in the Graham Hospital, Canton, of hypostatic pneumonia.

William John Reed, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1906; aged 66; died, October 10, in the Queen of Angels Hospital of coronary occlusion and essential hypertension.

James Carson Fountain, Columbus, Ohio; Starling Medical College, Columbus, 1906; served during the World War; on the staff of the White Cross Hospital; aged 63; died, November 3, of heart disease.

Robert Mayrand, Quebec, Que., Canada; Laval University Faculty of Medicine, Quebec, 1901; served during the World War; formerly professor of dermatology at his alma mater; aged 64; died, October 7.

Moss Young Allen, Mount Airy, N. C.; Medical Department of Tulane University of Louisiana, New Orleans, 1898; aged 68; died, October 31, at the Martin Memorial Hospital of cerebral hemorrhage.

Tandy Allen Hughes, Denver; St. Louis Medical College, 1883; at one time secretary-treasurer of the state board of medical examiners; aged 81; died, November 2, in St. Joseph's Hospital of pneumonia.

William Henry Garrison, Clarksville, Ga.; Atlanta School of Medicine, 1909; member of the Medical Association of Georgia; aged 57; died, November 10, in the Downey Hospital, Gainesville.

Charles Leidy Bossert * Atlantic City, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1908; served during the World War; aged 68; died, November 13, of heart disease.

John Reid Edwards, Madison, Wis.; Medical College of Virginia, Richmond, 1940; resident, State of Wisconsin General Hospital; aged 25; was killed in November in an automobile accident.

Artemas W. Chase * Adrian, Mich.; Detroit College of Medicine, 1900; formerly mayor; served during the World War; on the staff of the Bixby Hospital; aged 66; died, November 7.

Frank W. Lee * Osage, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1887; aged 82; died, October 28, in the Cedar Valley Hospital, Charles City, of uremia.

James L. Bow, Whitewright, Texas; Louisville (Ky.) Medical College, 1893; member of the State Medical Association of Texas; aged 76; died, November 4, at Wichita Falls.

William Erastus Judson, Livermore, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1907; aged 63; died, August 10, in Oakland of uremia.

Shelton Idolia Colvin, Gibsland, La.; Memphis (Tenn.) Hospital Medical College, 1891; aged 73; died, September 5, of injuries received when he was struck by a truck.

Elzora Butler Allen, Raymond, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1904; aged 67; died in September in a hospital at Madera of carcinoma.

Leon Octave Noel, Sherbrooke, Que., Canada; Laval University Faculty of Medicine, Quebec, 1883; aged 82; died, October 15, in the Hopital Notre-Dame, Montreal.

Frank P. Head, Gallatin, Tenn.; Vanderbilt University School of Medicine, Nashville, 1898; aged 65; died, November 4, of cerebral hemorrhage and arteriosclerosis.

Edward Ferris Holbrook, San Francisco; Cooper Medical College, San Francisco, 1893; member of the California Medical Association; aged 69; died, October 9.

John H. Lowery, San Diego, Calif.; University of Louisville (Ky.) Medical Department, 1894; aged 68; died, October 3, of diabetes mellitus and arteriosclerosis.

Joseph Domenic Reeng, San Francisco; Cooper Medical College, San Francisco, 1909; member of the California Medical Association; aged 54; died, October 28.

Joseph Ridgway, Minneapolis; Minneapolis College of Physicians and Surgeons, 1894; died, October 29, of arteriosclerosis and myocardial insufficiency.

Allister McDonald Murray, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1908; died, October 29, in the Toronto East General Hospital.

Lawrence Hobbs Acres, Los Angeles; Stanford University School of Medicine, San Francisco, 1930; aged 38; died, August 21, of upper respiratory infection.

William Clarence Doyle, Windsor, Ont., Canada; Western University Faculty of Medicine, London, 1901; at one time mayor of Essex; died, September 17.

Melvin McKinley Lofton ☉ Philadelphia; Howard University College of Medicine, Washington, D. C., 1922; aged 44; died, October 7, of heart disease.

Morris Fink ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1906; aged 59; died, October 31, of coronary thrombosis.

Wendell H. Priest, Mitchell, Neb.; John A. Creighton Medical College, Omaha, 1910; aged 58; died, October 26, in the Fairacres Hospital, Scottsbluff.

William Moore White, Lenoir, N. C.; Atlanta (Ga.) College of Physicians and Surgeons, 1899; formerly county health officer; aged 80; died, October 31.

Joseph Walter Kean, Los Angeles; Jefferson Medical College of Philadelphia, 1906; aged 57; died, August 30, of coronary occlusion and arteriosclerosis.

Albert C. Buell, Cleveland; Homeopathic Hospital College, Cleveland, 1880; aged 90; died, November 10, of bronchopneumonia and coronary sclerosis.

Alonzo Graves, Russellville, Ala.; Marion-Sims College of Medicine, St. Louis, 1899; veteran of the Spanish-American War; aged 67; died in October.

William Wright McEwen, San Diego, Calif.; St. Louis College of Physicians and Surgeons, 1883; aged 87; died, September 4, of coronary occlusion.

John Riley Hughes ☉ Milwaukee; Rush Medical College, Chicago, 1912; served during the World War; aged 55; died, October 26, in Oakland, Calif.

Epaenetus Luther Trimmer ☉ Los Angeles; Jefferson Medical College of Philadelphia, 1897; aged 78; died, August 13, of aortic regurgitation.

Archie E. Carder, Coweta, Okla.; Beaumont Hospital Medical College, St. Louis, 1901; aged 77; died, October 30, of carcinoma of the prostate.

Norman Beard Noll, Mercer, Pa.; Jefferson Medical College of Philadelphia, 1902; aged 63; died, October 29, in New York of cerebral hemorrhage.

Carl S. Gunther Nagel, San Francisco; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1881; aged 83; died, October 27.

Alexander Franklin Brown, Fort Sumner, N. M.; Vanderbilt University School of Medicine, Nashville, Tenn., 1890; aged 82; died, October 8.

John Rollin Harrison, La Porte, Texas; College of Physicians and Surgeons, Keokuk, Iowa, 1892; aged 83; died, November 5, in Houston.

Will Sayer Moffatt, Los Angeles; Hahnemann Medical College and Hospital, Chicago, 1868; aged 94; died, September 12, of arteriosclerosis.

Harvey Milton Mayer, Los Angeles; Medico-Chirurgical College of Kansas City, Mo., 1905; aged 67; died, August 17, of ventricular fibrillation.

William Silas Hewitt, Cincinnati; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; aged 72; died, November 9.

Moses Krakowski ☉ New York; University of Kharkov Faculty of Medicine, Russia, 1894; aged 74; died, October 31, of coronary occlusion.

Hammond Johnson McCallum, Azusa, Calif.; University of California Medical Department, San Francisco, 1895; aged 71; died, October 15.

Madeline E. Johns, San Francisco; University of California Medical Department, San Francisco, 1903; aged 72; died, September 10.

Matthew Francis Desmond, Burney, Calif.; University of California Medical School, San Francisco, 1923; aged 47; died, August 10.

Robert Lee Fulcher, Blanco, Texas; University of Tennessee Medical Department, Nashville, Tenn., 1897; aged 72; died, October 1.

Gordon Edward Helston, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1922; aged 41; died, October 14.

John William Haines, Croton, Ohio; Starling Medical College, Columbus, 1896; aged 70; died, November 4, of myocarditis.

William S. Ambler, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1893; aged 79; died, October 15.

Richard C. Cartwright, Kingston, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1884; aged 79; died, October 20.

Edgar Moses Brundage, Chaplin, Sask., Canada; Baltimore Medical College, 1896; also a dentist; aged 79; died, October 2.

Richard A. Stark, Chicago; Jenner Medical College, Chicago, 1908; served during the World War; aged 55; died in October.

Frank Webster Terwilliger, Highland, N. Y.; Dartmouth Medical School, Hanover, N. H., 1896; aged 71; died, October 31.

Owen Abner Buck Ames, Fairfield, Maine; Dartmouth Medical School, Hanover, N. H., 1898; aged 65; died, November 9.

William Axel Johnson, Santa Cruz, Calif.; Chicago College of Medicine and Surgery, 1916; aged 70; died, August 31.

James Albert Ghent, San Francisco; Trinity Medical College, Toronto, Ont., Canada, 1889; aged 72; died, September 1.

Charles Wilbur Monroe ☉ Cincinnati; University of Cincinnati College of Medicine, 1934; aged 40; died, November 4.

Joseph Franklin De Castro, Brooklyn; Bellevue Hospital Medical College, New York, 1885; aged 81; died, November 2.

Melvin Clinton Kimball Sr., Tulsa, Okla.; American Medical College, St. Louis, 1908; aged 61; died, November 2.

James Edward McCue, San Francisco; Cooper Medical College, San Francisco, 1901; aged 73; died, October 30.

Henry Edgar Vreeland, Los Angeles; Rush Medical College, Chicago, 1891; aged 86; died, October 24, of senility.

Paul Heron Reilly ☉ Vallejo, Calif.; Cooper Medical College, San Francisco, 1901; aged 77; died in October.

Joseph Crane Kessler, Hamlin, W. Va.; Illinois Medical College, Chicago, 1908; aged 67; died, October 28.

William Lustig, New York; Long Island College Hospital, Brooklyn, 1906; aged 57; died, October 29.

James P. Atkinson, Bodcaw, Ark. (licensed in Arkansas in 1903); aged 80; died, October 11, of carcinoma.

Charles Henry Buchanan, Chicago; Rush Medical College, Chicago, 1876; aged 90; died, November 12.

Bureau of Investigation

EDWARD S. HIDDEN AND SOME FAKES "Tonic," Obesity "Cure" and Hair "Grower" Subjects of Federal Actions

Edward S. Hidden of New York first came to the attention of the Bureau of Investigation in March 1939 as a shipper of a nostrum, "Vitatic," which was seized in interstate commerce by the Food and Drug Administration. The shipment was found to be a violation of the national Food and Drugs Act because of false and fraudulent representations on the labels. Among these were that the product was a "body builder . . . wonderfully efficient for rundown people . . . will tone up your entire system by bringing about the proper coordination of your stomach, liver, kidneys and bowels and by supplying your body with the necessary essentials it now lacks. . . ." Government chemists reported that Vitatic consisted essentially of extracts of plant drugs including nux vomica and an emodin-bearing drug (not named), with alcohol (14.4 per cent by volume) and water. As no claimant appeared, judgment of condemnation was entered and the product ordered destroyed. The resulting Notice of Judgment (No. 29764) was briefly abstracted in THE JOURNAL, Dec. 9, 1939, page 2168.

Following the confiscation an information detailing the nature of the violation was directed against Edward S. Hidden and the case was transmitted to the United States Attorney General for consideration. Subsequently at the trial in New York City in September 1940 a jury found Hidden guilty on three counts and he was fined \$600, from which verdict he filed an appeal, it was reported. The judge's charge to the jury was said to have been particularly strong. It was reported also that Hidden had been convicted in New York of violating the sanitary code for having in his possession and for sale an unregistered "patent medicine" and a harmful drug; that he was sentenced to six months imprisonment and served two and a half months of this sentence before being released on bail after filing an appeal, which is said to be still pending.

The Post Office Department was the next government agency to look into one of Hidden's schemes. This was the mail order sale of a "fat cure," variously known as "Slim-A-Lax" and "Tab Thins" and represented to reduce excess weight safely, quickly and easily without diet or exercise and regardless of the cause of the obesity. According to a government chemist, it consisted of pink-coated tablets, each essentially a mixture of ginger, podophyllin, aloin, cascara and small amounts of strychnine and belladonna. As an expert medical witness for the government pointed out, its effect was a laxative one. In other words, it was one of the pernicious treatments that reduce weight by hurrying the food through the system before it can be assimilated. Further, it was shown that Hidden's nostrum was not "absolutely safe and harmless" as claimed. He presented no defense either in person or through any representative, and a fraud order was issued on Oct. 25, 1940 against the names under which he had operated the scheme: Madison Chemical Company, Tab Thins Company, Slim-A-Lax Company, Riverside Chemical Company and C. N. Talcott.

Meantime the Post Office had been investigating another mail order activity of Edward S. Hidden. This was an alleged baldness cure called "Nuhair," in the sale of which he did business under his own name, also as C. J. Walton, Nuhair Company and Nu Hair Company. The Post Office charged that Hidden represented that Nuhair was a scientific discovery, that when used as directed it would produce a full growth of hair even when the user was "as bald as a billiard ball" and that it would overcome various scalp disorders. The usual testimonials, of course, were employed as part of the promotional scheme. At the hearing of the case it was brought out that, according to the Nuhair label, the product contained water, sulfonated castor oil, kerosene, 60 per cent of alcohol and 0.1 per cent of beta naphthol, and a government chemist's analysis confirmed this composition. An expert medical witness for the government testified that the ingredients of Nuhair are not new but have been commonly used in hair treatments and their actions and

limitations are well known; that baldness may be due to many systemic causes not affected by any type of treatment, and that Nuhair was worthless as a hair grower. On Jan. 28, 1941 a fraud order was issued which debarred from the mails the business conducted by Edward S. Hidden, C. J. Walton, the Nuhair Co., Nu Hair Company, and their officers and agents, none of whom had appeared or put up a defense at the hearing of the case.

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Absorbine, Jr.—In March 1941 the Federal Trade Commission accepted from W. F. Young, Inc., Springfield, Mass., a stipulation in which this concern promised to discontinue the following misrepresentations in the sale of its products: That "Absorbine, Jr." can kill such fungi of athlete's foot as are buried beneath the corneous layer of the skin, have any effect on tissues deeper than those supplied by the peripheral vascular system, or that accepted laboratory tests have proved that it achieves such results. Nearly four years previously (June 1937) the Young concern had stipulated with the Federal Trade Commission that it would no longer advertise Absorbine, Jr. as a treatment for insomnia.

Mothersill's Seasick Remedy.—This is put out by a Ferd. T. Hopkins, trading as Ferd. T. Hopkins and Son, New York. In March 1941 he signed a stipulation with the Federal Trade Commission in which he agreed to cease advertising that the product will prevent or stop travel sickness or assure travel comfort. When analyzed in the American Medical Association's Chemical Laboratory a good many years ago, the treatment was found to consist of capsules whose chief potent ingredient was chlorobutanol.

Rumagol.—This is put out by one A. Medrano, Los Angeles, trading as the Rumagol Laboratories, Rio Grande Pharmacy and Rio Grande Drug Company. In March 1941 Medrano entered into a stipulation with the Federal Trade Commission in which he promised to cease making these misrepresentations for "Rumagol": That it is an effective treatment or analgesic for rheumatoid arthritis, muscular pains, lumbago, sciatica, gout, neuritis, arteriosclerosis, painful or twisted joints or nerves or so-called rheumatism, that competing products are ineffective in the treatment of such ailments or that the preparation will reduce and eliminate excess uric acid by its action on the kidneys. Medrano further agreed to discontinue advertisements which fail to reveal that Rumagol should not be used when abdominal pain, nausea, vomiting or other symptoms of appendicitis are present or that frequent or continued use of the product may result in dependence on laxatives.

Schenck's (Dr.) Mandrake Pills.—J. H. Schenck and Son, Inc., Philadelphia, promised the Federal Trade Commission in March 1941 that it would discontinue advertisements which fail to reveal that these pills should not be used when abdominal pain or other symptoms of appendicitis are present or that frequent or continued use of the product may result in dependence on laxatives.

Thymo Borine.—In March 1941 the Thymo Borine Laboratory, Milwaukee, stipulated with the Federal Trade Commission that it would no longer advertise that this alleged mouth wash, deodorant and antiseptic purifies the breath, mitigates inflammation of the mouth resulting from artificial teeth and stops perspiration odors or foot odors; that it is a competent treatment for itching scalp or itching skin due to bites, poisons, hives or athlete's foot and is an effective germicide when used as a gargle.

Vimm Products.—Mariano Pollina of New York for a time operated as Vimm Wheat Germ Products Company and Moderno Company, distributing alleged health food products. In March 1941 he signed a stipulation with the Federal Trade Commission stating, among other things, that he had sold his interest in the two trade names and the food products to a corporation. He agreed that, should he ever resume the advertising and sale of these products, he would not in any way represent that "Vimm's Wheat Germ Oil Capsules" will assure good health or normalize, strengthen, revive or prolong reproductive functions; that "Vimm's Wide Wheat Germ" is the world's richest natural source of vitamins B, E and G, a good source of vitamins A and C and is concentrated with iron, copper, potassium, magnesium and manganese or any of these elements; that "Fertile Palm Co." will prevent tooth decay, premature aging, nervousness, acidity and is essential for growing children and pregnant women or that "Plain Palm Co." assures digestive vigor, is a perfect natural food containing the greatest possible concentration of vital factors from plants in digestible form.

Correspondence

SURGICAL VS. MEDICAL TREATMENT OF HYPERTENSION

To the Editor:—The paper by Woods and Peet (*THE JOURNAL*, November 1, p. 1508) needs careful study and perhaps additional comment in order to emphasize certain points. The important question is whether or not to recommend surgical treatment for patients with hypertension. Both in their own series and in the series of Wagener and Keith from the Mayo Clinic which they use for comparison, the percentage of cases classified as group 4 (malignant hypertension) is much higher than that found in private practice. Their own series is stated to be 32 per cent and the Mayo group 67 per cent. To a great extent, therefore, they are not discussing the kind of cases that comprise most of the cases of hypertension seen in private practice.

The majority of patients with hypertension seen in private practice have a moderately high blood pressure and a moderate degree of arteriosclerosis of the retinal vessels and would fall into their group 2. One must be particularly impressed, therefore, that their surgical results in this group are the same as the medical results as far as mortality is concerned.

From a practical point of view, then, the survival of patients with the most common form of hypertension with which the practitioner deals is not influenced by this form of surgical treatment.

In their group 3 it seems questionable whether they are talking about the same kind of patients as those in the Mayo series. They do not attempt to differentiate between patients who have arteriosclerosis of the retinal vessels and those who have simply angiospasm, and yet it is obvious that this is an important difference as far as end results of any treatment is concerned. Moreover, in the revision of the classification which they offer they do not attempt any differentiation within this group as far as arteriosclerosis and angiospasm are concerned. When a patient with hypertension has arteriosclerosis of the retinal vessels, especially if it is pronounced, it is an indication of long-standing hypertension with probable changes in vital organs due to corresponding arteriosclerotic changes.

Therefore, one may question whether the comparability of group 3 has been established for the two series of cases. This in turn affects the evaluation of mortality. Moreover, when one compares their table 4 B, which has to do with mortality, with table 1, one finds that in this same group 3 the Mayo Clinic had a percentage of only 17 females while they had 43, and it is well recognized that women tolerate hypertension better than men.

It is their group 4 (cases of papilledema) in which noteworthy therapeutic results seem to have been achieved. If their cases in this group correspond to the Mayo group 4 and do not include cases of acute angiospastic hypertension, which sometimes subside spontaneously, then surgery of at least this form of hypertension is amply justified.

The last point is one to which I have called attention before, and that is the fallacy of judging symptomatic relief following operation as a criterion to justify operation, when blood pressure figures and other objective evidences have not been influenced. It is obvious that this is no criterion at all and by no means constitutes an indication of the value of surgery as opposed to medicine. Many therapeutic procedures besides surgery may bring about symptomatic relief in hypertensive patients.

May I offer the following classification of retinal changes from the standpoint of judging therapeutic results, if that is to be the only criterion:

1. Normal.
2. Arteriosclerosis without angiospasm.
3. Angiospasm without arteriosclerosis.
4. Both arteriosclerosis and angiospasm
 - (a) with no evidence of active retinitis and
 - (b) with evidence of active retinitis (hemorrhages and exudates).
5. Arteriosclerosis, angiospasm, retinitis and papilledema.

This is the first thorough effort of which I know to compare results of medical and surgical treatment by a long time follow-up of a number of carefully studied cases and for that reason deserves a great deal of credit.

EDWARD WEISS, M.D., Philadelphia.

[NOTE.—The letter of Dr. Weiss was referred to Dr. Max Peet, whose reply follows:]

To the Editor:—May we first express our appreciation to Dr. Weiss for the keen interest he has shown in our paper and for his penetrating criticisms, indicating a thorough knowledge of the therapeutics of hypertension.

The question is not at all a matter of "surgical versus medical treatment of hypertension" but rather of determining the point in the progress of the disease when surgical treatment should be called on to replace accepted medical treatment which has failed. In confirmation of this point of view may we agree with the author that we do not see "the kinds of patients who comprise most of the cases seen in private practice" but instead are asked to treat those patients who have not gained relief after a thorough trial of medical treatment. The term "versus" arises only when persistent medical therapy has proved inadequate for too long and has allowed irreversible damage to occur to the patient. It should be pointed out that to expect the neurologic surgeon to relieve the hypertension in such a case is exactly the same as to ask the general surgeon to operate on a patient whose appendix has been allowed to rupture.

In order to obviate the criticism that our cases in group 3 were not the same type as those in the Mayo series we have, in our article, presented a careful analysis of these cases and have, in addition, had assurance from Dr. Keith that they were correctly placed in group 3. We feel, therefore, that this criticism is unjustified.

To proceed to the next point of criticism, our statistics with regard to the difference in mortality between the sexes are misquoted. The correct figures for group 3 are: In table 1 (number and sex of patients) the percentage of males in the Mayo series is 58, in our series 33½; the percentage of females in the control series is 42, in ours 66%. (The figures quoted by the author of the letter are for total percentages, not for each sex). Regardless of this error, the argument that the two series are not comparable because we include more females is still tenable, provided the statement is true that "it is well recognized that women tolerate hypertension better than men." In anticipation of this criticism we have pointed out in our original article that "careful analysis of table 4 B demonstrates a relatively small difference in mortality between the two sexes in the control group." Actual figures for group 3 show no difference in mortality, revealing a 91 per cent mortality for males and a 93 per cent mortality for females in the control series as against a 36 per cent male and a 36 per cent female mortality in our series. The conclusion, therefore, should be reached that the idea that women in this group tolerate hypertension better than males must be revised and, for that reason, it must also be concluded that our mortality statistics can accurately be compared with those of the control series.

We should like to assure the author that our group 4, as stated in our article, includes only, by definition, those patients with papilledema. Patients with "acute angiospastic hypertension" without papilledema were not included in group 4.

We must disagree with the statement that symptomatic relief following operation "is no criterion at all." Although we state in our paper that "we have not emphasized symptomatic relief following operation," and we fully realize the difficulty in evaluating such relief after therapy, still to us the large percentage of patients (approximately 85) who did gain benefit symptomatically is of definite significance. This significance becomes greater when it is realized that the majority of these patients came because of symptoms which were unrelieved by accepted medical treatment.

The suggested classification of retinal changes is a good one. We shall not discuss its merits and shortcomings here, since we have a paper about to be published in which we discuss the great need for a standardized method of pretherapeutic classification and post-therapeutic evaluation of results and include a newly proposed classification of the retinal changes in hypertension which incorporates the modifications suggested in the letter.

MAX M. PEET, M.D.

WARD W. WOODS, M.D.

Ann Arbor, Mich.

ON THE ENZYMATIC HYPOTHESIS OF RADIOSENSITIVITY

To the Editor:—An editorial comment (*THE JOURNAL*, September 20, p. 1020) discussed some observations by W. M. Dale: The Effect of X-Rays on Enzymes, *Biochem. J.* **34**:1367 [Nov.] 1940) on the roentgen inactivation of purified enzymes in dilute solution. Under these conditions a large fraction of the activity of the specimen could be destroyed by doses of radiation even smaller than those used in radiotherapy.

The hypothesis that cellular damage produced by roentgen rays may be a consequence of the inactivation of intracellular enzymes has recently been regarded as untenable because of the enormous doses required for inactivation in experiments with crude concentrated enzyme preparations. The results of Dale with purified enzymes have again brought forth the suggestion that enzyme destruction in cells may after all play a part in determining the sensitivities of different tissues to roentgen rays.

In this connection it is interesting to consider some observations by us (Luria, S. E., and Exner, F. M.: The Inactivation of Bacteriophages by X-Rays: Influence of the Medium, *Proc. Nat. Acad. Sc.* **27**:370 [Aug.] 1941) on the roentgen inactivation of bacteriophages suspended in different mediums. These observations suggest an explanation of Dale's results, but at the same time they bring renewed doubt as to whether enzyme inactivation by roentgen rays can take place in living cells to an appreciable extent.

In the action of roentgen rays on bacteriophages, two distinct mechanisms were found and were interpreted one as an indirect and the other as a direct effect of the radiation. In dilute water and saline suspensions relatively small doses of radiation inactivate large amounts of bacteriophage. This effect appears to be due to an inactivating agent produced by roentgen rays in the medium. Among other reasons for this interpretation is the fact that the effect depends on the composition of the medium. The presence of small amounts of foreign proteins (suspensions in broth or in water solutions of gelatin, albumin and the like) greatly increase the resistance of bacteriophages. The presence of foreign proteins protects the bacteriophage presumably by competing with it in reacting with the agent produced in the medium by roentgen rays. A mere screening effect can be excluded on the basis of the known mechanism of roentgen absorption.

With large doses of roentgen rays—far larger than any used in therapy—bacteriophage is inactivated even in the presence of proteins. The characteristics of this inactivation process, in contrast with those of the effect in water or saline solution, indicate that it is a direct effect of the radiation on the bacteriophage particles.

There is published evidence that at least some other viruses in their sensitivity to roentgen rays follow a pattern similar to that observed with bacteriophages (Syverton, J. T.; Berry, G. P., and Warren, S. L.: The Roentgen Irradiation of Papilloma Virus (Shope): II. The Effect of X-Rays upon Papilloma Virus in Vitro, *J. Exper. Med.* **74**:223 [Sept.] 1941. Friedewald, W. F., and Anderson, R. S.: Influence of Extraneous Protein and Virus Concentration on the Inactivation of the Rabbit Papilloma Virus by X-rays, *ibid.* **74**:463 [Nov.] 1941).

The inactivation of enzymes in pure and in crude preparations can easily be interpreted in terms of the behavior of viruses as just outlined. The action of roentgen rays on enzymes in pure preparations, as observed by Dale, is doubtless an indirect effect, as indicated by its dependence on concentration. Earlier observations (Hussey, R. G., and Thompson, W. R.: The Effect of Radioactive Radiation and X-Rays on Enzymes: I. The Effect of Radiation from Radium Emanations on Solutions of Trypsin, *J. Gen. Physiol.* **5**:647 [May] 1923. Clark, H., and Northrop, J. H.: The Inactivation of Trypsin by X-Rays, *ibid.* **9**:87 [Sept.] 1925) on trypsin can readily be accounted for by the same mechanism. Moreover, the high resistance of the proteolytic enzymes studied by Dale, when acting on their substrates, may easily be interpreted as due to the protecting action of proteins.

Though it may seem paradoxical, the more a virus or an enzyme is purified the more the direct effect of radiation is overshadowed by the indirect and the more radiosensitive the material appears to be. In the case of enzymes, it is unlikely that a direct effect of radiation has ever been observed. If existing, it would probably become observable only with doses of several million roentgens, on account of the small molecular size of enzymes.

In view of the evidence presented here, it is difficult to accept the indirect action of roentgen rays on enzymes, as observed by Dale with purified material, as an explanation of the radiosensitivity of cells. As pointed out by Friedewald and Anderson in another connection, protoplasmic fluid, being rich in protein, would be expected to protect enzymes from the inactivating agent produced in water by roentgen rays. Only through some other process as yet unrecognized could enzymes in tissues be inactivated by therapeutic doses of roentgen rays.

PHONOGRAPHIC RECORDS OF HEART SOUNDS

To the Editor:—My attention has been called to an editorial comment in *THE JOURNAL*, October 18, which speaks of Dr. Geckeler's reproductions of heart sounds on phonographic records. You make the statement that he "no doubt conceived the technic." I thought that you might be interested in knowing that we have on file at the Army Medical Museum records of heart sounds prepared and deposited with us by Dr. Benjamin Manchester of Washington, D. C., in 1939. I understand that Dr. Geckeler knew of these records.

J. E. ASH, Colonel, Medical Corps, U. S. Army;
Curator, Army Medical Museum, Washington, D. C.

Wisconsin September Report

The Wisconsin State Board of Medical Examiners reports the oral and practical examination for medical licensure held at Madison, Sept 11, 1941 The examination included 10 questions An average of 75 per cent was required to pass One candidate was examined and passed Five physicians were licensed to practice medicine by reciprocity The following schools were represented

School	PASSED	Year Grad	Number Passed
Marquette University School of Medicine	(1941)		1
School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine	(1937)		Arkansas
University of Illinois College of Medicine	(1934), (1937)		Illinois
Boston University School of Medicine	(1933)		Maine
University of Wisconsin Medical School	(1938)		Wyoming

Tennessee October Report

The Tennessee State Board of Medical Examiners reports the written examination for medical licensure held at Memphis, Oct 1-4, 1941 The examination covered 10 subjects and included 100 questions An average of 75 per cent was required to pass Nineteen candidates were examined, 16 of whom passed and 3 failed The following schools were represented

School	PASSED	Year Grad	Number Passed
Temple University School of Medicine	(1939)		1
University of Tennessee College of Medicine	(1941, 15)		15
School	FAILED	Year Grad	
Long Island College of Medicine	(1940)		
University of Tennessee College of Medicine	(1941, 2)		

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Syphilis Transmitted by Blood Transfusion; Statute of Limitations.—The patient gave birth to a child June 26, 1930. The attending physician became alarmed at her loss of blood and summoned the defendant physician to give a transfusion. The patient's brother volunteered to supply the necessary blood and the defendant used it without testing for syphilis. The defendant did not see the patient again until March 1931, prior to which time it had been discovered that she was infected with syphilis, allegedly the result of the blood transfusion. There was evidence that the defendant, on March 26, agreed to cure the patient of her syphilitic condition and treatment was instituted. The patient died, however, April 2, following an injection of nearsphenamine. Thereafter, on Feb. 14, 1933, the administrator of the patient's estate brought suit against the defendant. Pending the action, the defendant died and his executor was substituted as a party defendant. The trial court directed a verdict for the defendant and the plaintiff appealed to the Supreme Court of Errors of Connecticut.

The complaint in this case asserted three distinct bases of recovery: first, damages for the death of the patient caused by the defendant's negligence; second, damages "for the disease," for the mental and physical suffering of the patient and for the expenses incurred by reason of the defendant's negligence in the transfusion of blood, and, third, damages for the breach of an agreement to cure the patient. The defendant's answer was in effect a general denial, and by way of special defense it was contended that the applicable statute of limitations had barred each count of the complaint. Section 5987, of the General Statutes of Connecticut provides that an action surviving to or brought by an executor or administrator for injuries resulting in death, whether instantaneous or otherwise, or whether caused by the negligence of the defendant or by his wilful, malicious or felonious act, must be brought within one year from the neglect complained of or from the commission of the wilful, malicious or felonious act. Section 6016 provides that an action to recover damages from any physician, surgeon, dentist, hospital or sanatorium for malpractice, error, mistake or failure to effect a cure must be brought within two years from the date of the accrual of the right of action. There is apparent confusion among the authorities, the Court said, as to when the statute of limitations begins to run in actions for malpractice. The general rule, however, is that in a case in which the injury was inflicted at the time of the operation and not occasioned by subsequent treatment or neglect, and there has been no fraudulent concealment by the physician, the period of limitation for actions commences from the date of the wrongful act or omission, although its results may not then have developed. An action for malpractice presents a claim of a hybrid nature, the Court pointed out. In one aspect it may be viewed as based on negligence; in another aspect as based on breach of contract. The term malpractice itself, continued the Court, may be applied to a single act of a physician or to a course of treatment. The statute of limitations begins to run when the breach of duty occurs. When the injury is complete at the time of the act, the statutory period commences to run at that time. When, however, the injurious consequences arise from a course of treatment, the statute does not begin to run until the treatment is terminated.

In the present case, the evidence was undisputed that the defendant physician was not the regular attending physician of the deceased at the time that her child was born. He was called in to perform the blood transfusion and after he performed the transfusion his services to the patient ceased and he did not see her again until March 1931. It follows, the Court said, that so far as the complaint sought to recover damages for the death of

the patient, caused by the defendant's negligence, the applicable statute of limitation under the laws of Connecticut was one year; the death having occurred in April 1931 and the action having been commenced in February 1933, this cause of action was barred. So far as the complaint sought to recover damages for the "disease," the mental and physical suffering of the patient and the expenses incurred by reason of the defendant's negligence in transfusion of blood, this cause of action was barred by the two year limitation contained in section 6016 of the General Statutes, the transfusion having occurred on June 26, 1930 and the action having been commenced on Feb. 14, 1933.

The right of action for death, if it was the result of a breach of contract to cure, would run from the day the death occurred, for that was the final termination of the defendant's contract, the final and complete breach. An action for death due to a breach of contract survives, the Court said, and since the death occurred on April 2, 1931, and the action was commenced on Feb. 14, 1933, the two year period prescribed by section 6016 of the General Statutes had not elapsed. There was evidence, the Court pointed out, that the death followed immediately after the injection of nearsphenamine in the course of the treatment administered to the patient by the defendant, and if the jury believed that the defendant agreed to cure the patient it might have found the defendant liable for that death. In the opinion of the Supreme Court of Errors, therefore, the trial court erred in directing a verdict for the defendant and a new trial was ordered.—*Giambozi v. Peters*, 16 A. (2d) 833 (Conn., 1940).

Malpractice Insurance: Breach of Express Contract to Cure Not Covered by Policy.—The physician plaintiff was insured by the defendant insurance company against loss from claims for damages "on account of any malpractice, error or mistake" by the plaintiff. During the life of the policy the plaintiff expressly agreed to remove certain blemishes from a patient's face. The plaintiff's treatment having failed to remove the disfigurements, the patient sued the plaintiff for breach of express contract and the physician effected a settlement with the patient. Subsequently the plaintiff sued the defendant insurance company to recover the amount of the settlement and the counsel fees he had incurred in defending the patient's action. From a judgment for the insurance company, the physician appealed to the supreme court, appellate division, first department, New York.

The plaintiff contended that the policy written by the defendant was broad enough to cover liability for damages arising from the breach of an express contract to cure. Medicine, said the appellate court, is not an exact science and physicians know they cannot warrant a cure. If a physician does so warrant, as the plaintiff did here, and fails, he is liable for breach of contract even though he used the highest possible degree of professional skill. The legal liability in such a case is entirely different from that arising through "malpractice, error or mistake," which was the contingency provided for in the policy issued by the defendant, and it was with respect to that contingency and that contingency alone that the defendant agreed to save harmless the physician from claims for damages. Judgment for the defendant was accordingly affirmed.—*Safian v. Aetna Life Ins. Co.*, 24 N.Y.S. (2d) 92 (New York, 1940).

COMING MEETINGS

- Annual Congress on Industrial Health, Chicago, Jan. 12-13. Dr. C. M. Peterson, 535 North Dearborn St., Chicago, Secretary.
- American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Diveley, 1103 Grand Ave., Kansas City, Mo., Secretary.
- Society of American Bacteriologists, Baltimore, Dec. 29-31. Dr. J. L. Budd, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Society of Surgeons of New Jersey, Trenton, Jan. 28. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- *Influence of Physical Work on Physiologic Reactions to Thermal Environment. C. E. A. Winslow and A. P. Gagge, New Haven, Conn.—p. 664.

Influence of Aminoacetic Acid on Muscular Strength.

—Horvath and his associates determined the grip strength of 8 men twice a day for eleven weeks. Four subjects received 6 Gm. of aminoacetic acid (glycine) daily for eight weeks, 2 received it for four weeks and then placebos and 2 served as controls for nine weeks and then 1 of them was given 12 Gm. of amino-

acetic acid daily for two weeks. Improvement in the strength of the subjects receiving aminoacetic acid was no greater than that of those given placebos. Creatinine or creatine excretion showed no changes attributable to the ingestion of aminoacetic acid.

Reactions to Thermal Environment and Physical Work.

—Winslow and Gagge studied the reactions to various atmospheric conditions of 2 unclothed men performing active physical work on a bicycle ergometer at such a rate as to increase their metabolism to more than 300 Kg. calories per hour. The radiation area was the same as that for the resting subject, approximately 70 per cent of the body surface area. The convection constant of a subject pedaling at a rate of some thirty revolutions per minute was increased in cooling power to an air movement of 30 to 40 cm. per second. The increased secretion of sweat, with consequent evaporative cooling, balanced perfectly with the increased heat which must be dissipated as a result of the high metabolism. The evaporative regulation of the working subject operates so effectively that the cutaneous temperature is constant. Actually it is lower for the working than for the resting body. It seems that under these circumstances the internal temperature and not the cutaneous temperature must control the sweat-secreting mechanism. Maximal comfort is experienced by both working and resting subjects at about 2 degrees C. (3.6 degrees F.) below the point at which active secretion of sweat begins.

Wernicke Syndrome.—Jolliffe and his associates review the data on the 27 patients with Wernicke's syndrome admitted to Bellevue Hospital from 1935 to 1940. In 3 the condition was of nonalcoholic origin; 2 were depressed and refused to eat, and 1 had pulmonary tuberculosis associated with vomiting. However, the fact that in all the reported cases the disease occurred in malnourished persons suggests that the syndrome is of nutritional rather than of toxic or alcoholic origin. Peripheral neuropathy was present in 25 patients, and in each it preceded or accompanied the ophthalmoplegia. The precedence or concomitance of this syndrome tends to confirm Alexander's con-

tention that less thiamine hydrochloride is required to protect against angiodegeneration than is necessary to preserve the functional integrity of the peripheral nerves. In addition to peripheral neuropathy encephalopathy due to nicotinic acid deficiency was observed in 9 patients, stomatitis due to nicotinic acid deficiency in 9, dermatitis due to nicotinic acid deficiency in 3 and riboflavin deficiency in 1. Thirteen patients recovered, and 12 of these were left with a residual Korsakoff syndrome, which does not show a consistent response to thiamine hydrochloride as has frequently been claimed.

Narcolepsy.—From a study of the electroencephalograms of 22 narcoleptic patients Dynes and Finley observe that the waking records of 17 were normal, as were those of the 16 who had attacks during the electroencephalographic recording, that is, the patterns were in all instances similar to those observed during the physiologic sleep of normal persons. The patterns of the remaining 5 patients were atypical or abnormal, suggesting that the neurophysiologic disturbance was more widespread. The fact that abnormal waking patterns differed in these 5 patients suggests that the location or the character of the lesion also differed in each case.

Azosulfamide in Epilepsy.—Cohen and Cobb describe the results that they obtained in 10 patients with severe epilepsy with the anticonvulsant dye disodium 4-sulfamidophenyl-2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3', 6'-disulfonate (azosulfamide). The results do not establish this drug as an efficient aid in the treatment of epilepsy, but they do suggest the possibility. The sulfamidamide fraction appears to be the important one in producing the anticonvulsive effect. There is no evidence to suggest whether the effect is due to "direct" or "indirect" action on the nervous system. Either or both are possible. It is possible that the effect produced is due to the property sulfamidamide possesses of inhibiting the action of carbonic anhydrase.

Vitamins to Prevent Common Cold.—Spiesman observed 54 sufferers from the chronic cold for one to three winters; 7 were given massive doses of vitamin A, 7 vitamin D and 40 both vitamins. He found that neither vitamin A nor vitamin D when given separately had any immunizing effect on the incidence or severity of the patients' colds, but that when massive doses of the two vitamins were given together the number and the severity of the colds of 80 per cent of the subjects were significantly reduced. Vitamin therapy for the common infectious cold is not offered as a panacea. Average susceptibility and the emotional state of the subject as affected by an innately unstable vasomotor mechanism must be considered.

Sinusitis in Swimmers.—During the last ten years 23 patients with acute fulminating sinusitis or its complications, according to Maxwell, have been admitted to the University Hospital; in 22 the infection extended into the calvarium or the intracranial contents, and in 13 the disease was apparently due

to swimming. Diffuse osteomyelitis occurred in 2, epidural abscess in 1, subdural abscess in 1 and abscess of the frontal lobe of the brain in 8. After surgical procedures all the patients recovered except 1, whose death on the second day after a Killian operation was attributed to massive cerebral edema associated with an unsuspected abscess of the frontal lobe. Bacteriologic studies demonstrated a growth of staphylococci in all except 2 patients; for these there was no bacteriologic report. Because of the staphylococcal origin of most of these fulminating infections, the early use of sulfathiazole is urged. It is proposed that the cause of acute fulminating sinusitis after swimming is the introduction of virulent organisms into a normal sinus which has not had the advantage of instituting local barriers to infection. The rapidly appearing signs of intracranial complications in acute fulminating sinusitis suggest that intracranial infection is established by the time frank sinus suppuration appears, and therefore the rationale of draining an acutely infected frontal sinus within the first few days to prevent intracranial complications is questioned.

Carcinomatosis of Bone Simulating Pernicious Anemia.

—Markowitz believes that the premortem diagnosis of carcinomatosis of bone simulating pernicious anemia would be made more often if the possibility was borne in mind, especially when the compensatory blood changes do not follow intensive treatment with liver extract. He cites a case in which there were the typical blood changes which simulate pernicious anemia and the other factors which should refute such a diagnosis. The patient, a white woman aged 60, complained of prolonged weakness and pains in the legs. She had been treated with liver extract. While a differential blood count was being made 16 normoblasts and 5 per cent myelocytes were encountered. There was a moderate disproportion in the erythrocytes, with increasing numbers of macrocytes and moderate poikilocytosis. The most compatible diagnosis was pernicious anemia, and blood transfusion was administered and liver extract was given subcutaneously and orally, but after two weeks of treatment there was little change in the blood picture. The diagnosis was questioned, but before much more could be done the patient died, three weeks after treatment with liver extract was begun. At necropsy essential pathologic changes were observed in the stomach and the bone marrow. The stomach was of normal size, but along the greater curvature, in about the midportion, there was an elevated rounded tumor. Microscopic examination revealed a typical adenocarcinoma. The bone marrow was

bright red and was interspersed with small purple-gray areas. On microscopic examination large groups of tumor cells were seen to have invaded the bone. The strands of marrow tissue in some areas were rich in myelocytic cells. The large number of myelocytes and normoblasts was not typical of primary anemia. This, together with the history of previous liver therapy with no apparent benefit, should suggest carcinomatosis of the bone marrow.

Effect of Grape Juice on Intestinal Flora.—Portis and Fishbein determined the effect that grape juice had on the intestinal flora of 50 institutionalized but normally active patients. The amount of gram-positive organisms was definitely increased by the daily ingestion of 24 ounces (720 cc.) of grape juice divided into three doses. The increase could be maintained by the daily ingestion of 8 ounces (240 cc.). Few if any acidophilus bacilli, as determined by stool cultures, were found in the stools of patients before grape juice was added to the diet. However, after its continued use a definite increase in the number of acidophilus bacilli was observed. The 50 subjects tended to constipation, and most of them had to resort daily to drastic laxatives, but after grape juice was added to the diet none suffered from constipation and none used laxatives during the experiment. Since gram-positive organisms are a factor in calcium metabolism it is possible that an increase in calcium absorption occurs in the intestinal tract in an aciduric medium. Furthermore, if an aciduric flora inhibits the growth of proteolytic organisms, there may be some relation between the change of flora and the absence of the so-called intestinal toxemia.

Intracranial Lesions and Sudden Death.—Among 234 cases of sudden death Swift and Moersch found that in 22 death was due to intracranial conditions: in 18 to hemorrhage, in 2 to tumor, in 1 to infarction and in 1 to epilepsy. Immediate death from intracranial causes is rare. A few patients lived from ten to thirty minutes after the fatal episode; most of them lived from one to five hours. Cardiac hypertrophy was present in 78.9 per cent of the cases of intracranial hemorrhage and infarction. The most common symptom complex consists of severe sudden headache often associated with vomiting, stiff neck and sudden coma, especially when the hemorrhage is profuse. Other diagnostic features are convulsive seizures,

either focal or general in character, dilatation of the pupil on the side of the hemorrhage and generalized spasticity. Hemiplegia may be present in cases of either intracranial hemorrhage or thrombosis. Syphilis did not seem to play any special part in sudden death caused by intracranial lesions.

March Hemoglobinuria.—Recently Gilligan and Blumgart encountered 3 patients with march hemoglobinuria; in 1, an insurance broker, the hemoglobinuria developed on repeated occasions during short, brisk walks, and in the other 2 patients, college athletes, it developed during strenuous runs of one and a half and five miles. The athletes showed albuminuria at no time except after strenuous runs, and in the insurance broker it developed only at the time of hemoglobinuria or after a walk sufficient to produce hemoglobinemia. Two of the patients had slight chronic icterus, most evident in the scleras. The authors point out that their studies and those of other investigators suggest that "physiologic" hemoglobinemia and hemoglobinuria occur more commonly than their infrequent diagnosis suggests. March hemoglobinuria will now, perhaps, be observed more frequently because of the present strenuous military training. It is important to differentiate this relatively benign condition from the serious conditions that may lead to hematuria.

Chronic Low Grade Fever of Local Origin.—Shannon believes that the possibility that regional warmth due to infection in the nasal sinuses may produce an elevation of oral temperature in children has not been sufficiently emphasized. As a result many such children are erroneously thought to have a generalized low grade fever and are forced to suffer the consequences. In such cases the general body temperature as recorded at the rectum is normal.

Sulfathiazole for Decubital Ulcers.—Goodman and Corsaro pulverized the commercially available sulfathiazole tablets and applied the powder daily, by means of a salt shaker, to the decubital ulcers of 5 chronically ill patients. The ulcers previously had been treated unsuccessfully by other accepted

methods, one for as long as twenty-one months. The quantity of the drug used varied with the size of the ulcer, as sufficient powder to coat the ulcer completely was utilized. The actual amount varied from 1 to 3 Gm. During treatment with sulfathiazole all other treatment, except light cradles or infra-red lamps, was withdrawn. Almost immediately after the sulfathiazole powder was applied the infection cleared up and clean, healthy granulation tissue, followed by healing of unwonted rapidity, appeared. The authors' success with these local lesions led them to use the method for 1 patient with chronic osteomyelitis, 2 with traumatic indolent ulcers of the feet, 1 with draining fistulous tracts in a recently amputated stump and 1 with a stubborn pilonidal sinus. Healing was rapid and complete in each patient.

Atypical Typhoid Infections.—According to Lantin and his colleagues, among 6,000 patients with typhoid 23 had atypical febrile periods, 11 had a fever for not more than ten days and 12 had a febrile period of not less than sixty days. The authors believe that if the condition of such patients is not recognized early they can become dangerous sources of typhoid organisms which may lead to serious epidemics. The fever of the first 11 patients was moderately high and of a variable curve type. Anorexia, abdominal pain, vomiting, chills, tympanism, nausea and articular pains were accompanying symptoms. Slight intestinal hemorrhage, occurring in 1 patient, was the only complication observed. All the patients had a complete and uncomplicated recovery. A definite diagnosis was made on the evidence of positive hemoculture. The protracted fever of the 12 patients lasted from sixty-one to one hundred and fifty-seven days; in the 3 who recovered it averaged ninety-seven days. The fever was prolonged, high, continuous and of a variable curve type. The principal accompanying symptoms were headache, delirium, semiconsciousness and abdominal pain. Complications were many and varied: toxic myocarditis in 10, severe toxemia in 8, pulmonary complications in 7, typhoid asthenia in 4, intestinal hemorrhage in 3, acute hepatitis in 1, acute

cholecystitis in 1 and peripheral neuritis in 1. The mortality was 75 per cent. The diagnosis in 4 was based on positive hemocultures and on the necropsy observations of the other 8. Active typhoid lesions were observed at the necropsy of the 9 patients who died.

Inactivation of Group Specific Isoagglutinins.—Davis tried to determine the fate of incompatible isoagglutinins when they are transfused into the blood of a recipient in the form of plasma, serum or ascitic fluid. In vitro studies showed that the isoagglutinins present in plasma, serum or ascitic fluid could be inactivated by appropriate mixture with a fluid containing opposing isoagglutinins. A mixture of group A and group B plasma in equal proportions inactivated the isoagglutinins in both plasmas so that neither agglutinated erythrocyte suspensions. Such inactivation is greater at a temperature of 37 C. than at lower temperatures. Since temperature plays an important part in isoagglutinin inactivation, incompatible plasma, serum or ascitic fluid should be heated to body temperature before transfusion. The transfusion of cold incompatible biologic fluids is more apt to result in incomplete isoagglutinin suppression, with a resultant agglutination in vivo. Likewise, a rise in temperature of the blood of the recipient, as in fever, might accelerate the phenomenon of inactivation and thereby prevent in vivo agglutination of transfused incompatible fluids. When the isoagglutinin titers of any two biologic fluids are unknown the greatest degree of inactivation of the isoagglutinins will occur if equal volumes of the fluids are used; thus when one is pooling fluids the volume factor should be kept in mind.

Pain in Cyclic Vomiting.—Karelitz and Blumenthal recommend antiketogenic therapy for differentiating the acute abdominal pain of cyclic vomiting from that of appendicitis with vomiting. In the first instance the abdominal discomfort and tenderness become less and the fever and the leukocytosis diminish, whereas in acute appendicitis the abdominal symptoms become more distinct, the tenderness persists and localizes and the fever, tachycardia and leukocytosis continue. In all cases in which the diagnosis is obscure treatment of the ketosis and deranged circulation by continuous intravenous administration of dextrose in saline solution should continue until the diagnosis is clear.

Pulse Rate in Acute Juvenile Rheumatism.—Glazebrook and Thomson recorded the pulse rate of 100 boys from 15 to 20 years of age during the first four weeks of their acute rheumatism. All the patients showed tachycardia in the later stages of the disease. Among the 100 boys there were 30 who had subnormal pulse rates in the acute stages of the illness; in another 32 the increase was less than that expected from the rise of temperature. Bradycardia was more common in those suffering from their first attack. The pulse depression of 18 occurred within the first four days of the illness. The depression bore no relationship to the temperature. As the bradycardia followed most types of treatment it cannot be said that the treatment or a vitamin B or C deficiency was a contributing factor. It appears that a depressed pulse in the early stages of the illness is of grave prognostic significance. Permanent cardiac damage developed within six months in 12 of 15 boys with a depressed pulse early in the disease. The authors regard a pulse depression in some cases as an index of the severity of the toxemia and feel that it is due to the action of streptococcus endotoxins.

Notes on Common Skin Diseases: III. Ringworm of Scalp, Favus. N. C. Dey.—p. 416.

Toxic Complications of Sulfanilamide Therapy.—Rajam and Rao discuss the complications that occurred among the 6,070 male and female patients treated with sulfanilamide at the venereal clinic of the Government General Hospital during the last three years. There were 1,765, or 29.08 per cent, reactions; some of them in order of frequency were fever, giddiness, nausea with or without vomiting, headache, muscular weakness, anorexia, numbness and tingling of fingers and toes, abdominal pain, pain in the chest, dermatitis, breathlessness with or without cyanosis and gastrointestinal upsets. Four types of fever, usually occurring between the fifth and tenth day of treatment and either alone or associated with dermatitis, leukopenia or breathlessness, were encountered: (1) a low intermittent fever, the temperature being rarely beyond 101 F., with an evening rise and a morning remission, lasting for a few days; (2) a sudden rise of temperature to 103 or 104 F., preceded by a chill and coming down by crisis in about twenty-four hours; (3) a fever similar to the second except that it continued for about three days and subsided slowly on or about the fourth day, and (4) shivering followed by a temperature of 104 or 105 F. the patient being very ill and toxic and having profound granulocytopenia. The toxic complications were almost equally distributed between the sexes with a preponderance of blood dyscrasias among women. The incidence of granulocytopenia in women was 1:500, whereas in men it was 1:5,000. With the exception of granulocytopenia the other toxic manifestations can be recognized by daily careful observation. It is the authors' opinion that sulfanilamide and its derivatives should be used with greater resolution than they have heretofore and that clinicians should not hesitate to administer the drugs in therapeutically adequate doses when the patients are under daily and careful control.

Mester's Test in Diagnosis of Rheumatism.—Cerviá and García López call attention to the immunobiologic reaction which Mester developed for the differential diagnosis of rheumatism. It is an intradermal test with a 0.1 per cent solution of salicylic acid, that is, four or five papules are produced with 1 cc. of this solution and the leukocytes are counted before and thirty and sixty minutes after the intradermal injection. The reaction is regarded as positive if the leukocyte count shows a reduction of 10 per cent or more after the injection. The mechanism of the reaction supposedly is like that of Widá's hemoclastic crisis. The authors employed this method in 32 subjects. Of 18 patients with rheumatism or with a history of this disease 88 per cent showed positive results, independent of the activity of the process or of the administration of salicylate. Of 14 control patients without signs of rheumatic disease 2 had positive reactions. Although the method is simple and of clinical value, it has the disadvantage that the intracutaneous injection of salicylic acid is extremely painful.

- *Quantitative Determinations of Sulfapyridine in Blood for Control of Clinical Effects. L. R. Ganem.—p. 779.

Quantitative Determinations of Sulfapyridine in Blood.—Ganem made determinations of the concentration of sulfapyridine in the blood of 35 patients who had 1 Gm. of the drug three times a day, up to a total amount of 20 Gm. in seven days. The author observed that the concentration of sulfapyridine in the blood depends on the capacity of absorption of the digestive tract and on the functions of the kidney. Lack of the drug in the blood or a low concentration indicates lack of absorption or a poor capacity of absorption. Concentrations as high as 20 mg. for each hundred cubic centimeters of blood can be observed in patients with renal diseases. Good results were obtained by the author when the concentration of the drug did not exceed 9 mg. Therefore a concentration of 10 mg. should be regarded as the greatest concentration necessary for obtaining good results from the treatment. According to the author the concentration of sulfapyridine in the blood should be determined in all cases. A concentration of more than 10 mg. per hundred cubic centimeters is an indication for diminishing the dose or stopping sulfapyridine treatment. Accidents from sulfapyridine therapy are caused by the administration of a large dose or by hypersensitivity of the patient to the drug. They can be prevented by the administration of small doses.

Cutaneous Cancer Among Natives of East Indies.—Ten Seldam presents statistical data which show that cancer of the face is not less frequent among the natives than among the Europeans. The protection which the pigmented skin of the natives should provide against the biologic effect of the sun is lost by the great quantity of ultraviolet rays in tropical sunlight, and it is possible that other rays exert a carcinogenic action on the skin.

Book Notices

The Medical Aspect of Boxing. By Ernst Jökl, M.D., Head of Department of Physical Education, Witwatersrand Technical College, Johannesburg, South Africa. Cloth. Pp. 251, with 59 illustrations. Pretoria: J. L. Van Schaik, Limited, 1941.

The material of this volume is divided into two general parts: immediate effects of injuries in boxing, and remote effects of such injuries. The former part deals with the physiology and pathology of different injuries such as the chin knockout, the solar plexus knockout, the heart knockout and the carotid sinus knockout, all due to legal blows. The author produces some evidence to show that the chin knockout, the most common of the four, is due to injury to the medulla chiefly by contre-coup. It differs from the concussion of football and other sports unless the head of the injured boxer strikes the floor. There follows a brief discussion of such conditions as "grogginess" which fall short of the severity of a knockout. The latter part deals with the pathology of delayed effects of repeated blows on the chin, head or other parts. There are citations of numerous cases including some fatalities in the ring, due, in almost every instance, to repeated injuries in former fights.

The author's conclusion, from the medical point of view, is that the dangers inherent in boxing are sufficient to warrant its discontinuance. However, from the human point of view, he feels certain that it will not be discontinued and therefore suggests some protections and precautions.

The book concludes with a number of tables and an extended bibliography. It is well written although somewhat unusual in arrangement, but the field covered is so limited that its chief use will be as a library reference work.

Coming of Age. By Esther Lloyd-Jones, Ph.D., Professor of Education, Teachers College, Columbia University, New York, and Ruth Fedder, Ed.D., Guidance Counselor, Cheltenham Township Public Schools, Elkins Park, Pennsylvania. Cloth. Price, \$2.50. Pp. 280. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1941.

This book centers its primary interest in human growth as a part of the process of reaching maturity. Although it is primarily written for young people, many parents will appreciate it in their quest for a way of helping their children to find and give a rich and satisfying life. Professional persons in all varieties of work with young folk will welcome its sound insight, common sense and lack of dogmatism. Personality patterns are drawn realistically and objectively with analyses of family interrelationships and the part each member plays in the whole as well as one member on another. The sum of these observations is a clear picture of the family group as it operates in shaping the personalities of its members. The young person can use this material to help clarify his own picture of himself, both as he has been affected and as he affects others. The parent can find guidance in seeing more clearly the implications of his responsibility to his children.

The first chapters deal with the psychologic factors that go into the forming of personality. Examples are given of the different ways in which individuals meet their needs within their own particular life situations. Emphasis is given to the part played by insecurity and unsureness of self and how this expresses itself differently in different individuals. In growing up, young people must know the necessity of accepting limitations and of developing the abilities they possess.

Growing up inevitably involves adjustments which are discussed in separate chapters—the family, the love relationship, college, vocation. The family group provides the first experience with giving and sharing and as such is the foundation on which later adjustments are based. The home should have provided opportunities for freedom of choice and for carrying responsibility so that a young person will learn to meet emergencies and new situations "with security, poise and stability."

A chapter on men, women and love concerns itself primarily with the distinction between true love and sex attraction and the problems young people express in relation to this. A discussion brings out several concepts, mainly that true love develops slowly, grows as the relationship grows. True happiness can blossom from physical attraction, but the basis for it must be something much more real and lasting. Mature love

implies freedom for each individual and therefore necessitates unselfishness, a real sharing of common interests and growth in understanding one another.

Chapters on college and on vocation show the young person discovering himself further in relation to his own needs and sharing with others and lead to the final chapter, "What Can We Believe?" This chapter, which begins "The most distinctive characteristic of man is his quest for values," brings the book to a truly inspired conclusion. Man's eternal quest for goals—for purpose in life—is discussed. Perhaps the sentence that more than any other describes the spirit and purpose of this book is "A person cannot be considered mature until he has, somehow, learned to develop an internal authority that gives him a sense of personal responsibility for making choices in the light of the best he knows."

Principles of Microbiology. By Francis E. Collen, B.S., M.S., Ph.D., Associate Professor of Bacteriology and Preventive Medicine in the Creighton University School of Medicine, Omaha, and Ethel J. Odgaard, R.N., A.B., M.A., Instructor in Sciences Applied to Nursing, College of Saint Teresa, Winona, Minnesota. Cloth. Price, \$3. Pp. 444, with 153 illustrations. St. Louis: C. V. Mosby Company, 1941.

The task of teaching the student nurse the fundamentals of the preclinical sciences sufficiently well to underwrite intelligent practice is one that is beset with many difficulties. These are, of course, inherent in the writing of a textbook such as the present one, which is directed primarily toward this end, and account in large part for the superficial and fragmentary presentation this volume has in common with most other textbooks in this field.

The content is much the same as that of the usual medical textbook of bacteriology, but the material is rigorously cut and put in the simplest terms. The book is divided into seven sections. The first is an extended introduction which includes a discussion of the general biologic aspects of the bacteria and related organisms as well as a consideration of technics. The second and third sections, both short, are devoted to sterilization and disinfection and to bacterial variation and classification respectively. The fourth is a general consideration of infection, immunity and hypersensitivity. The fifth, and by far the largest, consists of chapters devoted to the pathogenic bacteria, viruses, rickettsiae and pathogenic fungi and protozoa. The sixth section is a consideration of the bacteriology of water and milk, and the seventh an appendix made up of formulas of culture mediums, suggested laboratory exercises and a glossary.

In general this material is up to date and clearly presented, though failure to include at least brief discussions of more recent work, such as that on spirochetosis of dogs in relation to Weil's disease, active immunization to tetanus, and the pneumococcus types comprising group IV, detracts somewhat from this general impression. The extreme degree to which the material has been condensed results in the creation of some false impressions. It is implied, for example, that the chlorination of sewage is equal in importance to the chlorination of water. Similarly it is stated that sugars are unstable to autoclaving and that sugar broths are always sterilized by the intermittent process, the last at variance with common practice in most laboratories in the case of the most frequently used sugars. It is stated also that the fermentations of the staphylococci are definite, whereas these bacteria include a wide variety of physiologic types.

In a number of instances statements are made which are open to some question. Few bacteriologists, and those the life cycle enthusiasts, would agree with the delineation of a "typical" life cycle illustrated on page 133 or the discussion on page 137, for the material presented as established fact is far from being generally accepted. Regarding the epidemiology of poliomyelitis, the statement that "the virus . . . is thought to enter through the respiratory tract. Epidemiological studies . . . have shown that the mosquito probably plays some part in the transmission of the disease" is hardly a fair one when it is all that is devoted to this matter. It is suggested that the proprietary organic mercury compounds are excellent disinfectants, comparing favorably with tincture of iodine, an obvious fallacy. Some may object to the use of the generic name *Torula* for the asporogenous yeasts, for *Cryptococcus* is generally used in the medical literature.

In the reviewer's opinion many of these faults could have been ironed out through a rearrangement of the subject matter, making use of space wasted in the extended treatment of water and milk in chapter 13, which is devoted to an unimportant discussion of nursing and microbiology, and elsewhere for a somewhat more rounded presentation of the essential material. In general, however, the presentation is an accurate and balanced one considering the difficulties under which the authors labored.

The book is profusely illustrated, eighteen of the plates being in color. The latter are uniformly good and some, such as those illustrating the cutaneous reactions, should be very useful. The book is somewhat underindexed, though the index is a good one; in a textbook of this sort it would be better to over-index slightly. The type is clear and well printed; there are remarkably few typographic errors for a first edition.

This book will probably prove to be a useful and welcome addition to nursing education textbooks; the physician will find it almost completely useless because of its elementary nature.

Society and Medical Progress. By Bernhard J. Stern. Cloth. Price, \$3. Pp. 264. Princeton: Princeton University Press; London: Oxford University Press, 1941.

The author's point of departure is "that medicine, both as a science and a profession, is inextricably bound up with the social process and with scientific developments in other fields." It shares in the cyclic movements of industry, government and education. "The long road to medical science" is built round or over or blasted through vested interests, superstition, bigotry, tradition, quackery, astrology and other obstacles to human progress. Medicine advances most rapidly when it is closest to the life of humanity and stagnates in scholasticism. These truths are told well and illustrated thoroughly, making a work of fundamental value to all who are interested in society and medical progress. The historical is better than the contemporary treatment, although the chapters on urbanization, the conquest of famine, and income and health build a good foundation for an understanding of many present problems. Emphasis is placed on the part played by "tools," buildings, institutions—on everything but the increased knowledge of the physician in the diagnosis and treatment of disease. There is frequent reference and condemnation of the "lag" between discovery and the application of medical advances but almost no mention of the ways by which organized medicine has shortened that lag through scientific testing, standardizing and endorsement or rejection of new developments. Universities and hospitals are given almost sole credit for fixing standards of medical education. It would seem that one significant "lag" has been overlooked—that between the author's knowledge and existing achievements of the medical profession.

Fundamentals of Comparative Embryology of the Vertebrates. By Alfred F. Huettner. Associate Professor of Biology, Queens College, Flushing, N. Y. Cloth. Price, \$4.50. Pp. 416, with 168 illustrations. New York: Macmillan Company, 1941.

This is an elementary textbook devoted primarily to the development of the frog, the chick and the fetal membranes of mammals. Only one feature justifies so feeble an addition to the field: this is a series of excellent new stereograms of the frog's egg and the chick embryo. The attempt to make a corresponding series of early stages of human development failed because of the author's lack of familiarity with normal material: his diagrams (figs. 158-163) have many and serious errors. A consideration of experimental work is excluded for lack of space, but there is no excuse for the failure to use the many significant interpretations of normal processes which experimental embryology has given us. The book begins with a detailed discussion of genes, which enjoy greater popularity among zoologists today than ids and idants enjoyed a generation ago. On page 46 one reads "that the chromosomes are the cellular differentiations which control growth and development is easily demonstrated . . ." This is surprising when one considers that most of the evidence furnished by the Morgan school deals with insignificant characters or with defects. Anatomic nomenclature is a matter of no significance in the author's estimation. He seems to think that most Greek and Latin plurals end in *i*. His use of terms such as perilymph and choroid plexus is astonishing, to say the least. The author's ignorance of the

adult structure and relation of the organs which he is following through ontogeny is reflected by various errors. Thus on page 301: "Since there is no body cavity in the neck or tail regions it is obvious why the sympathetic chains are lacking there." The ependyma is said to be differentiated as a distinct layer from neural fold stages on. The optic nerve fibers grow centrally, he says, "through the choroid fissure." On page 240 he writes as follows: "The brain progressively becomes relatively smaller in its development to the adult condition by pushing the successive divisions of the brain closer together, a process known as cephalization." The concept of differential growth never occurred to the author. He keeps harping on exceptions to the biogenetic law, failing to realize that most reminiscences of past racial history might have dropped out of vertebrate ontogeny as completely as they did from cephalopod development. The really significant thing is that there are recapitulations like the gill pouches and aortic arches in amniotes. The majority of human implantation sites selected for presentation were either abnormal or poorly preserved. The macerated Peters specimen is described as "probably the best preserved . . . of all human embryos"!

Oral Pathology: A Histological, Roentgenological, and Clinical Study of the Diseases of the Teeth, Jaws, and Mouth. By Kurt H. Thoma, D.M.D., Professor of Oral Surgery, Harvard University, Boston. Cloth. Price, \$15. Pp. 1,306, with 1,370 illustrations. St. Louis: C. V. Mosby Company, 1941.

This is a comprehensive coverage of oral pathology, easily the best in this field. It can be recommended without material reservation to both students and practitioners interested in and concerned with diseases of the mouth. The material presented by the author is inclusive without being unduly redundant. The longest chapters, about eighty pages each, deal respectively with modifications of growth and development, dental caries and tumors of the soft tissues. Each chapter is followed by a bibliography including liberal selection of pertinent articles from the literature, over two thousand in all; possibly there are too many, as there is little indication as to the relative value of the items cited. The illustrations are well selected from a wide range of material and add immeasurably to the value of the text. More than one third of these are reproduced from the work of other writers, but with their permission and due acknowledgment. The quality of these illustrations is generally high, although there is a wide margin between the best and the poorest. One objective of the author, to present adequately the evidence "that the tongue and oral mucosa constitute a barometer, a mirror which reflects the state of health of the patient," has been definitely attained. In no other place in the literature will such descriptions be found in such abundance. This includes not only disease in general but also especially blood dyscrasias, food deficiencies and diseases of the skin. Hereditary anomalies of the teeth and oral structures receive generous attention, including case histories and genealogical charts. All of this is done without any neglect of the usual subject matter of oral infections, tumors, dental caries or pyorrhea. There is an adequate index.

William Henry Welch and the Heroic Age of American Medicine. By Simon Flexner and James Thomas Flexner. Cloth, \$3.75. Pp. 339, with 26 illustrations. New York: Viking Press, 1941.

Here is a volume that has long been awaited by the medical profession, since it recapitulates the story of a great leader in the advancement of medical science and since the story is told by a distinguished pupil. Perhaps a single authorship would have made this a better book than it is, because its one failing seems to be the unevenness of the various chapters in their treatment of their subjects. Thus some of the chapters are highly scientific and profuse with technical terms; others have the same charming simplicity that characterized the book by James Flexner called "Doctors on Horseback." If there is any other fault of the volume it lies in its failure to recognize the human attributes of Dr. Welch which made it quite possible for him occasionally to fail in his objectives and which made it also possible that he might occasionally pursue an objective to a successful result without being willing to concede the dangers or the harm that might result from such a success. No doubt the passing of time will make possible a much more

scientific evaluation of Dr. Welch's work. The present volume is more than satisfactory as a record of his career and as a picture of the man.

Readers will learn with surprise that Dr. Welch really did not want to be a doctor, that his early inclinations were wholly toward education and the classics. Nevertheless he was descended from a line of physicians, and his decision to engage in medicine as a career met with the prompt approval of his family. His early education was supplemented by study abroad with men whose names are today associated with the fundamental studies that laid the ground for our modern knowledge of pathology and bacteriology. The mind of Dr. Welch was alert, full of curiosity, and was a scientific mind. Hence he sifted well from the vast diet that was laid before him. Nevertheless, just as Sir William Osler failed to recognize the great significance of the contributions of Pasteur, so also the great Welch seems to have failed to participate in the presentations of Robert Koch and spent his time in other studies which seemed to interest him more.

American leaders will want to read this book for its story of the beginning of the Johns Hopkins Hospital, for the innumerable contacts of William Welch with the great philanthropists who by their gifts probably did as much to force certain trends in American medicine as did the medical leaders who guided those trends. They will find great interest in the travels of Dr. Welch, and they will enjoy the inside story of the establishment of the Institute for the History of Medicine at Johns Hopkins University School of Medicine. The personality of Welch is revealed as that of a man whom many called "Popsy" behind his back but who knew him only as Dr. Welch in his official life. They will find that he was withal a lonesome man, whose influence and work still continue and have made a permanent record in American medical life. One finds that he was a great leader in the campaign against antivivisection. One would find the account more balanced if there were adequate mention of the part played by W. W. Keen in this work. One finds him credited for having established the first scientific medical journal in the United States; yet this seems hardly to recognize other contributions which were certainly in the field at the time when the *Journal of Experimental Medicine* was established. The preparation of this book undoubtedly included much research, and there is a long list of acknowledgments. There is also appended a record of the organizations with which Dr. Welch was associated, and the honors bestowed on him. There are many pages of notes documenting some of the statements made in the text, and there is an excellent index. The book stands in favorable comparison with the autobiographies and biographies which have during this year recorded for us the lives of the great faculty which made Johns Hopkins University School of Medicine the leading medical school for a considerable period in our country.

Modern Trends in Ophthalmology. Edited by Frederick Ridley and Arnold Sorsby. By J. Adamson et al. Cloth. Price, \$10. Pp. 699, with 271 illustrations. New York: Paul B. Hoeber, Inc., 1940.

This book is a compilation of material supplied by fifty-five different authors. Its purpose can best be described by quoting the editors' statements in the preface: "Clinical practice occupies a position in between the systematized knowledge (and some venerable fallacies) enshrined in textbooks, and the ferment found in the periodical literature. . . . Throughout the book it has been our aim to emphasize neither that which is already established, nor that which is as yet unformed, but to indicate emergent tendencies and formative influences." In accomplishing their purpose the editors have divided the material into seven sections: ophthalmology in relation to general medicine, diagnostic procedures, refraction and binocular vision, physiology of vision, some newer conceptions in pathology, treatment and social aspects. The editors have planned their book with foresight, and the contributors include many of the foremost ophthalmologists of our day writing on phases of the subject in which each is renowned. On the whole it can be said that the authors have succeeded admirably in fulfilling the aims which they have expressed. As inevitably must happen in a work of this type, certain of the chapters leave something to be desired while others are superb in their discussion of the material. Especially well handled are the chapters on allergy

and immunity in ophthalmology by Alan C. Woods, retinal and choroidal arteriosclerosis by Jonas Friedenwald, the intraocular pressure by Frederick Ridley, and hereditary and constitutional dystrophies of the cornea by Franceschetti and Streiff. This book is one which practicing ophthalmologists will find interesting but which beginners will hardly appreciate.

Psychogenic Factors in Bronchial Asthma. Part I. By Thomas M. French, M.D., and Franz Alexander, M.D. With the Collaboration of Catherine L. Bacon, M.D., et al. Psychosomatic Medicine Monograph IV. Paper. Price, \$2. Pp. 92. Washington, D. C.: National Research Council, 1941.

As quickly as the word was introduced into American medical circles, "psychosomatic" was given much lip service by many physicians and psychologists. Psychosomatic as applied to factors in a given case, as a branch of medicine or as a special type of research, is horribly misused and all too frequently misunderstood. This monograph on bronchial asthma may stand as a documentary definition of what is meant by psychosomatic, for it is a living model of investigation in that field.

The Chicago Institute for Psychoanalysis is exceptionally fortunate in its capacity for psychosomatic research. It commands a large clinical material on which the many cooperating analysts work, it enjoys adequate medical consultations and its directors have the vision with which to sift from the large quantities of superficial data presented at innumerable seminars by collaborators (twelve for this study) the specific psychologic factors in etiology. Yet organic factors are not overlooked or neglected. As French states, ". . . on the other hand there seems to be fairly general agreement among allergists that psychological and allergic factors may easily stand in a supplementary relationship to each other. In many cases at least it is not a question of either an allergic or a psychological etiology but of some sort of cooperation between them."

Concerning the psychologic component in the etiology, asthmatic attacks tend to be precipitated by situations that threaten to separate the patient from some mother figure, and in such a situation the asthma attack seems to have the significance of a suppressed cry. Such suppression is often the result of early demands for attitudes of independence and self sufficiency in childhood before the patient had developed such capacities. Many of the mothers were of the rejecting type. Situations which presented direct or indirect temptations toward independence evoked asthmatic attacks.

Although the number of adults and children studied in this research was quite large, the psychodynamic studies summarized are now open to statistical proof. Such fresh studies of large quantities of patients, of necessity studied superficially, must however be dynamically oriented and penetrate beneath the apparent realities of the actual precipitating factors. Many seemingly diverse situations may have in common temptation factors. It may be possible to institute short psychotherapy with good results based on a knowledge of these psychodynamics.

Internists and psychiatrists are strongly urged to study this monograph, for in the reviewer's opinion it represents a major contribution to psychosomatic research and therapy.

The Principal Nervous Pathways: Neurological Charts and Schemas with Explanatory Notes. By Andrew Theodore Rasmussen, Ph.D., Professor of Neurology, Department of Anatomy, University of Minnesota Medical School, Minneapolis, Minn. Second edition. Cloth. Price, \$2.50. Pp. 73, with 28 illustrations. New York: Macmillan Company, 1941.

Professor Rasmussen's splendid atlas is presented in a revised edition. Certain alterations in the localization of sensory tracts have been based on newer knowledge from surgical operations on human beings. The section on the diencephalon has also been revised. The drawings have been made with meticulous care and deserve thorough study. The book is highly recommended for students and specialists.

Psychiatry as a Career. Published by The Institute for Research, Chicago. The Institute for Research, Research No. 116. Paper. Price, \$1. No pagination, with illustrations. Chicago, 1941.

This little brochure is part of a series of articles written to answer questions of young men who are about to choose their careers. The material is written in easily understandable style, and the contents represent a fair and adequate statement of the psychiatrist's functions. It can be recommended to college students who show a beginning curiosity regarding psychiatry.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LOSS OF HEARING FROM DYNAMITE BLAST

To the Editor:—A gold miner was working in a raise with a stoping machine when dynamite was blasted from a place about 100 feet below and 20 feet away from the place where he was. The man suddenly felt dizzy and noticed he could not hear anything. He was treated at the company hospital, and after a few days hearing returned to one ear, but the other ear remained deaf six months afterward. This is a labor compensation case. Can the deafness be attributed to the blasting at the distance mentioned? What is the prognosis with regard to the return of hearing in the deaf ear?

Jose S. Santillan, M.D., Manila, P.I.

ANSWER.—Loss of hearing from an explosion may be due to rupture of the drum membrane, in which case the loss is not complete and recovery occurs as the drum membrane heals, or it may be due to trauma to the end organ of hearing in the labyrinth as a result of the sudden loud noise, in which case the hearing may be completely lost, but more often the impairment involves only part of the tone range and in the ensuing weeks there is generally partial recovery.

Complete and persistent loss of hearing following exposure to an explosion may occur in soldiers under shell fire on a functional basis (hysterical deafness).

In the case of the gold miner a complete examination of the ear and hearing with appropriate tests (Weber, Rinne, Schwabach and audiometer tests) to demonstrate the location of the lesion and the Stenger test to detect malingering should show which type of lesion this patient has suffered. The fact that the hearing has returned in one ear but not in the other speaks for an organic rather than a functional defect. After six months further improvement in an organic defect would not ordinarily be expected to occur. Whether damage to the ears could occur at the distance mentioned depends on the intensity of the blast. If workers are usually exposed to this sort of blasting at the distance stated without damage to the ears it would seem unlikely that the blast caused the deafness. There is, however, considerable individual variation in the susceptibility of the ear to acoustic trauma.

ONYCHIA AND DERMATITIS IN WORKER WITH CLEANING FLUIDS

To the Editor:—A man aged 28 has onychia. His occupation is that of a cleaner. This condition is most severe on both thumbs, and there is a rash on the thenar eminence of the left hand. The rash resembles eczema. There is no evidence of any disorder in the nervous system or infection or presence of foreign bodies. The Wassermann reaction is negative, and the patient appears to be in sound health. I have used the ordinary treatment for eczema with no results. I was formerly of the opinion that this irritation might be due to the solvent, made by the Du Pont Company, used in the cleaning business. The patient did not permit his hands to come in contact with this solvent for some time, and decided improvement was present. However, he continued to work in his place of business, and I was in doubt as to whether the inhalation of these fumes was sufficient to keep the inflammatory process active. I would appreciate your opinion and any suggestions as to further treatment.

L. H. Dunham, M.D., Scottsbluff, Neb.

ANSWER.—Both the dermatitis and the onychia may be the result of such occupational contact with a chemical solvent. It is not believed that a condition of this type could result from inhalation of fumes. It is most likely that the solvent, following repeated contact with the skin, has produced a dermatitis. Such dermatitis usually develops as a dermatitis venenata or simple contact dermatitis and becomes eczematized through repeated recurrence or chronicity. Solvents usually act as irritants both by removing the protective coating of natural oil and superficial epidermal cells, following which the skin is more vulnerable to all types of irritation including that caused by soap and water, or the solvent acts as a direct chemical irritant as a result of penetrating the pores or the epidermis itself. In chronic dermatitis of this type, onychia or nail changes of a dystrophic type frequently develop as a result of disturbance of nutrition of the growing nail at its matrix because of the dermatitis in the region of the nail. The observation that the condition improved following avoidance of contact with the solvent supports a diagnosis of occupational dermatitis and onychia. The possibility of onychomycosis or fungous infection of the nail must also be

considered, though the latter condition is not commonly observed and is usually associated with evidences of fungous infection elsewhere, particularly on the toes and involving the toenails.

When all the nails or the majority of the nails are involved, consideration must be given to possible constitutional or nutritional disturbances; but if the involved nails are only those on the thumbs or fingers that also exhibit dermatitis, then occupational dermatitis is more likely to be the cause.

The first and most important procedure in treatment is, of course, removal from contact with the irritant by change of work. If this cannot be carried out, protective measures should be followed whenever exposure to the solvent occurs, such as the wearing of rubber gloves or finger cots or bland protective creams and bandages. In the treatment of the dermatitis itself, when the condition is the result of an occupational irritant, bland creams are best, and where the solvent may have dried the skin excessively an ointment containing hydrous wool fat is usually desirable. It is not probable that the onychia will be responsive to treatment, but once the dermatitis has been healed normal nail growth is likely to occur. In a chronic phase of dermatitis, weak tar preparations in ointment form are likely to be helpful and, in dermatologic practice, small doses of unfiltered roentgen rays are frequently helpful but must be used cautiously to avoid permanent damage to the nail matrix.

ERGONOVINE IN LABOR

To the Editor:—Will you please give me information on the use of ergonovine intravenously at the end of the second stage of labor to prevent blood loss?

J. B. Carlyle, M.D., Burlington, N. C.

ANSWER.—Ergonovine is a powerful uterine stimulant and is rapid in action. It has been administered orally, intramuscularly and intravenously. The pharmacology of this drug has been investigated and a review may be found in the medical literature. About three years ago M. E. Davis and his associates at the Chicago Lying-in Hospital instituted, as an experimental procedure, the use of ergonovine administered intravenously at the end of the second stage. Davis suggested the following technic: When the baby's head has been delivered and the anterior shoulder has been brought into view, 0.2 mg. of ergonovine is given intravenously. Twenty or thirty seconds are allowed to elapse for the drug to take effect and then the baby is delivered. With the evacuation of the uterine cavity and under the influence of this powerful oxytocic, the uterus contracts down quickly, thereby separating the placenta from its attachment. At the same time the placenta is usually pushed out of the upper segment into the distended lower segment and vagina.

According to Davis (Postpartum Hemorrhage, *Am. J. Surg.* 48:154 [April] 1940) the intravenous use of ergonovine produces complete separation in most instances because of the effectiveness of the contraction of the uterine musculature. The sudden reduction of the placental area shears the placenta from the uterine wall during the initial contraction; the blood loss is thus reduced, and the incidence of third stage complications has been said to be greatly decreased. Rarely the separated placenta will be caught in a contraction zone at the junction between the upper and lower segments, and manual removal may have to be resorted to. This drug should be administered only in a hospital, as an assistant is needed to give the drug so that the obstetrician may devote his entire attention to the uterus and extraction of the placenta.

In some experimental animals ergonovine has been shown to be approximately one-fourth as toxic as ergotoxine and ergotamine. Although gangrene can be produced experimentally, no clinical reports have appeared describing the occurrence of gangrene in human beings following the use of ergonovine. Toxic symptoms closely resemble those produced by the older alkaloids of the ergot series.

PROGNOSIS IN CARCINOMA OF RECTUM

To the Editor:—I have made a diagnosis of primary adenocarcinoma of the rectum. The mass is at the rectosigmoidal junction. The patient was roentgenographed for every available part to which carcinomatous tissue commonly infiltrates; for example, the long bones of the body, the lungs, the stomach, the liver, the urinary bladder and the kidneys. The carcinomatous mass has been removed in toto. What would be the prognosis in such a case?

John B. Bellucci, M.D., Chicago.

ANSWER.—Statements as to prognosis in a case of primary adenocarcinoma of the rectum are difficult. In general, the prognosis depends on the age of the patient, the duration of symptoms, the size of the growth itself, the histologic type and whether or not spread has occurred to the regional lymphatics.

Papillary tumors have a better prognosis than infiltrating ones. Where the neoplasm has not extended through the muscular wall of the bowel, the prognosis is much better than when invasion through the serosa has occurred. Wide resection affords a greater chance for prolonged survival than more limited excisions. Recorded experience over the past several decades indicates clearly that improved methods of excision have afforded an ever increasing incidence of prolonged survival. Statistics for prolonged survival following apparently complete excision of rectal carcinomas vary considerably, the best being anywhere from 50 to 60 per cent of those surviving the operation. In series of unselected cases the five year survival is variously stated as 25 to 30 per cent of those surviving the operation. It would seem that the latter figure is conservative and might well represent the true situation with regard to these cases in general. The failure to recognize by clinical and roentgenographic examination evidences of metastases during the period shortly following operation would be of little significance in affording a prognosis, since satisfactory recovery from these operations and a period of apparent freedom from disease are only too often followed by development of metastases. Any patient surviving five years or more from resection of a primary adenocarcinoma of the rectum would appear to have an excellent chance for permanent "cure," unlike some other types of neoplasms in which five year survival does not necessarily indicate that recurrence or latent metastases may not subsequently manifest themselves.

MOTTLED ENAMEL FROM FLUORIDES

To the Editor:—What can be done to restore fluoride mottled teeth to normal whiteness? Is it possible to grind the surfaces of such teeth and cement porcelain caps over them? If such a procedure is possible, is it injurious to the teeth? What unfavorable complications might follow a properly performed operation of this type? If this work is done, where can I obtain a list of those competent to do it?

M.D., Texas.

ANSWER:—Because mottled enamel (endemic dental fluorosis) is a developmental enamel hypoplasia and because dental enamel is incapable of self repair during its post eruptive life, one should not expect even with the best known therapy that the enamel will be restored to normal translucency. A method of removing the brown stain from mottled enamel teeth, using a hydrogen peroxide-ether solution, has been described by Ames (*J. Am. Dent. A. & Dental Cosmos* 24:1674 [Oct.] 1937), which is reported to ameliorate this distressing condition considerably.

It is, of course, possible to remove the enamel and prepare the tooth for the reception of a porcelain jacket crown. An operation of this type for a tooth affected by mottled enamel should not involve any greater liability to the occasional pulpal devitalization or the recession of the gums than might follow in the case of a tooth not affected by mottled enamel. The preparation of a tooth for and the placement thereon of a porcelain jacket crown is routine practice for any well trained dentist.

In cases of even severe brown stain it would seem advisable to try first the brown stain removal therapy before recourse is had to the more radical porcelain jacket procedure. The attempt to remove the brown stain by grinding off the outer enamel surface followed by polishing or the inexcusable use of acid preparations in an attempt to remove brown stains are to be avoided because of the frequency of postoperative sensitivity to thermal changes.

It is not possible to furnish a list of those competent to remove brown stain from mottled enamel teeth, but it is thought that an inquiry to the dental society officials at either Amarillo or Lubbock (Texas) communities severely affected by mottled enamel might disclose the names of local practitioners experienced in this particular technic.

URETHRAL CARUNCLE

To the Editor:—What is the treatment for urethral caruncle?

M.D., Wyoming.

ANSWER:—The first step in the treatment of urethral caruncle is accurate diagnosis. Prolapse of the mucosa of the external meatus of the urethra frequently is erroneously regarded as a caruncle. Excision or cauterization of the prolapsed mucosa usually is followed by an eroded area, which often causes considerable distress and irritation. A caruncle usually can be demonstrated by the presence of a pedicle.

The best method of treatment of a caruncle is to clamp its pedicle with a fine, flat clamp applied as close to the urethral mucosa as possible. The protruding portion of the caruncle is then snipped off with scissors. Cauterization can best be accomplished by applying a standard solution of acid nitrate of mer-

cury to the basal tissues in the clamp. Care should be taken that the solution does not come in contact with the surrounding mucosa.

Incidentally, it should be remembered that many caruncles do not cause any symptoms and, if small, are frequently best left alone.

MONILIASIS AND VITAMIN DEFICIENCY

To the Editor:—Can you tell me of any work that has been published on the problem of producing a relative deficiency of one group of vitamins by overdosing of another group? What is known about overdosing in relation to any of the vitamins? A patient who manifested no obvious deficiency symptoms had taken thiamine hydrochloride 3 mg. a day for a year. She then started taking B complex 6 capsules a day, each capsule containing 333 international units of B₁, 500 micrograms of riboflavin, 130 micrograms of B₆, 10 mg. of nicotinic acid and 14 Jukes-Lepkovsky units filtrate factor. After about a month of this dosage the patient contracted a moniliasis of the mouth. I have wondered whether this infection may represent a deficiency of one of the other vitamins.

M.D., New York.

ANSWER:—It is not certain that moniliasis is a true manifestation of specific deficiency disease, although it is evident that in many people with B complex deficiencies various organisms of this type grow within the alimentary canal or in the mouth. In all probability they are secondary invaders.

There is indirect evidence that imbalance in medication with various B complex factors may lead to difficulties of one kind or another. The mechanism of this is not clear and it has not been shown that overadministration of one B complex factor produces a deficiency of another. However, there are two reported cases in the literature of pellagra developing after exclusive vitamin B₁ therapy (Braendstrup, Poul: *Pellagra Developing During Exclusive B₁ Therapy*, *Ugesk. f. læger* 102:95 [Jan. 25] 1940. Salvesen, Olaf: *Nord. med.* 5:297 [Feb. 17] 1940), but it cannot be assumed that in these cases pellagra would not have developed even if no thiamine had been administered. It is well known that evidence of thiamine deficiency may develop in patients with endemic pellagra during treatment with nicotinic acid if the diet is not improved or other B complex factors are not administered (Aring, C. D.; Evans, J. P., and Spies, T. D.: *Some Clinical Neurologic Aspects of Vitamin B Deficiencies*, *THE JOURNAL*, Dec. 9, 1939, p. 2105). There is a discussion of this problem in the 1941 Annual Review of Biochemistry (Morgan, A. F.: *Annual Review of Biochemistry*, 1941).

RECURRENT MYXOSARCOMA

To the Editor:—Two years ago a retroperitoneal myxosarcoma was removed from a woman in her early thirties. Its size was approximately 3 by 4 by 6 inches. It has now recurred, and its present size is again approximately the same. Can you advise me as to the prognosis and proper treatment? Is the roentgen ray used either as a complete treatment or postoperatively?

M.D., Minnesota.

ANSWER:—The prognosis and treatment depend on clinical and microscopic information that is not available in the data submitted. Roentgen therapy is used as a postoperative measure in operable lesions and as the sole treatment when the lesion is inoperable (Ewing, James: *Neoplastic Diseases: A Treatise on Tumors*, Philadelphia and London, W. B. Saunders Company, 1940).

ALLERGY TO SPERMATOZOA NOT PROVED CAUSE OF STERILITY

To the Editor:—Could a wife be allergic to her husband's sperm and could this be a cause of sterility? If this should be true is there any method of determining it? Is there any treatment (desensitization)? The young woman in question has had all types of tests and all give normal results. The oviducts are patent, the uterus is normal in size and the menstrual history normal, twenty-eight days, three to five day type with no dysmenorrhea. The husband's spermatozoa are highly motile and abundant in number. There is no history of contraceptives or acid douches being used. Could my opening question be a factor in the cause of sterility in such a case? If so, what can be done? Any suggestion would be appreciated.

M.D., Michigan.

ANSWER:—There is no sound evidence that a woman can become allergic to the spermatozoa of her husband. For many years animal experiments have been carried out in which the fertility was reduced or complete infertility established by the long continued parenteral injection of homologous semen. More recently, however, Eastman, Gutmacher and Stewart concluded, after a series of animal studies, that the injection of semen slightly reduced the fertility of the recipients but that the reduction was without practical importance.

Possibly some unknown factor is responsible for the infertility of this couple. Basal metabolic determinations on the husband and wife may warrant the use of thyroid. If air or gas was

used in establishing the patency of the oviducts, this procedure can be repeated after an interval of at least a year, using iodized oil. This will afford the opportunity to visualize the reproductive tract and furthermore it may enhance the possibility of gestation. When all the factors which tend to decrease fertility have been removed, gestation will probably result.

PURPURA

To the Editor:—A woman aged 38 in good health, with no evidence of the menopause as yet, has ecchymotic spots on various parts of her body at intervals of a few days. The first thing she notices is the onset of a sudden sharp, stinging pain, and in a few minutes a small swelling appears in this site, usually about $\frac{1}{8}$ to $\frac{1}{4}$ inch in diameter and slightly raised. A few minutes or hours later she notices a small black-blue area in the location where the swelling took place. These spots look like a small bruised area without tenderness. The lesions have appeared in various parts, but mostly on the arms or legs. In three or four days the discoloration disappears completely. I am at a loss to explain these lesions unless they are due to a sudden rupture of a small capillary, and if this is the case what would provoke such a condition? What can be done to prevent them? Is the condition serious and might such a condition occur in the brain? These spots occur one at a time, and never are there more than two in a period of a week or more.

M.D., Kansas.

ANSWER.—The lesions described are those of purpura. Since purpura is only a syndrome, it is necessary to obtain further data before the etiology can be established. A complete blood examination, including a platelet count, is essential. The prognosis and treatment depend on the cause.

If thrombocytopenia is present, it is important to determine whether it is primary or secondary in type. Among the more common causes of secondary thrombocytopenic purpura are leukemia, metastatic disease of the bone marrow and toxic depression of the marrow, as in aplastic anemias.

If the platelets are normal, the purpura may be idiopathic or secondary to various toxic conditions. Bleeding in the urine and stool may presage hemorrhages into the brain. Frequently, however, this condition is not progressive. Treatment is not highly satisfactory. Occasionally an allergic basis is present, foci of infection should be looked for, and finally some cases respond to endocrine therapy. In some cases, especially in women, the superficial veins appear to be unusually fragile, causing a harmless variety of purpura.

HALITOSIS FROM MAXILLARY SINUSITIS

HALTUSIS FROM MAXILLARY SINUS.
To the Editor:—I have had repeated attacks of bad breath for many years. I had my tonsils removed some years ago, with some improvement. Later, however, these attacks have seemed more frequent than usual. I have had constant sinus drainage that I know about since 1928. It is purulent in type, and to judge from roentgenograms and observable drainage it is confined largely to the left maxillary sinus. I have no symptoms other than drainage; there are no headaches and no pressure pain over the sinus area. Is such drainage sufficient to cause bad breath? Can you recommend measures to cure such a condition that offer more assurance of cure than just repeated operation for adequate drainage? Drainage seems profuse through the nose all the time, although I am aware that that does not drain the bottom of the sinus area.
 M.D., Texas.

M.D., Texas.

ANSWER.—It must be assumed that the diagnosis of chronic maxillary sinusitis on the left side is established. The purulent secretion present at all times can be responsible for repeated attacks of bad breath. This does not mean that a search should not be made for other causes.

Operative intervention properly carried out will give a satisfactory result in a large number of cases. Such intervention in the nature of a Caldwell-Luc operation is, as a rule, successful in the first instance. The object of the operation is not only to supply adequate drainage but to remove as far as possible all diseased mucous membrane. In only a small percentage of cases is it necessary to reoperate.

CHOCOLATE AND LEAD

CHOCOLATE AND LEAD

To the Editor:—Several times I have heard patients comment on the fact that there is lead in commercial chocolate, and they have asked me whether or not it is true and whether or not there is sufficient lead to be harmful. Apparently this has come from Consumers Research or some such organization. H. L. Mawdsley, M.D., San Mateo, Calif.

ANSWER.—Some years ago there was considerable discussion as to the amount of lead which can be obtained from eating chocolate. Small quantities can be found just as can be found in other foodstuffs, but as a result of this agitation chocolate manufacturers took great pains to eliminate any lead from their product as well as from the wrappers on the chocolate. It would appear safe to say that chocolate is as free as other foods from lead. Any processed food may have small quantities

of lead, either from the natural content of lead in the food or from small contaminations in the process of manufacturing, but these extremely minute quantities have never been shown to produce any deleterious effects in animals or in man.

PROGNOSIS AFTER CHOLECYSTOGASTROSTOMY IN INFANT

To the Editor:—An infant of 2½ months was operated on for obstructive jaundice at 3 weeks of age. An atresia of the bile ducts was present. A small gallbladder with clear bile was found, and a cholecystogastrostomy was done. A small amount of bile has been coming through the stool since. The icteric index has come down from 320 to 115. What is the usual course and prognosis in such a case? Should bile salts be given, and if so how much and what kind? Is any other medication or diet indicated?

M.D., New York.

ANSWER.—The presence of bile in the stools and decrease in the icteric index is definite evidence that the obstructive jaundice has been relieved. In all probability the condition will continue to improve with the growth of the child and in a few months should be entirely cleared up. There is, of course, the possibility that narrowing of the fistulous tract may come on, but this is not the usual course in these cases. If it does occur it can probably be relieved by secondary operation.

In the meantime it may be advisable to administer bile salts and an acceptable vitamin K preparation once a day until the jaundice has disappeared.

DENTAL EXTRACTIONS AFTER CORONARY OCCLUSION

To the Editor:—A man aged 57 was operated on two years ago for suppurative mastoiditis. At that time it was found that he had many chronically abscessed teeth and myocardial damage. On complete recovery from the mastoid involvement it was urged that he have proper dental care, which was done in a rather indifferent manner on his part. Two weeks after the extraction of a tooth a coronary occlusion followed. Please advise me as to how soon it could be considered safe to entertain the idea of removing the remainder of the abscessed teeth? The occlusion took place three weeks ago, apparently the posterior group. Progress toward recovery has to date been satisfactory. M.D., Virginia.

M.D., Virginia.

ANSWER.—It seems probable that the coronary occlusion was not associated with extraction of the teeth. The problem at the present time is to permit the complete recovery of the patient from coronary occlusion, and further extraction of the teeth should not be planned until there is no longer evidence of coronary change. Usually recovery sufficient for necessary extractions would occur in three to six months. In future extractions epinephrine in local anesthesia is to be avoided.

HAZARD OF TUBERCULOSIS IN SOUTHWEST

HAZARD OF TUBERCULOSIS IN SOUTHWEST
To the Editor:—A boy aged 11½ years during damp, cold weather, suffers from fleeting migratory neuralgic pains. This began two and one-half years ago. There is no evidence of rheumatic fever. His general condition is good. An ethmoiditis is present. He has been in Florida for the winter. I should like to take him to an area of low humidity, such as Tucson or Phoenix, Ariz., or Palm Springs, Calif. As there are supposed to be many cases of tuberculosis in these Arizona cities, would there be any danger in living there? Are latent or healed cases allowed in the public schools and, if so, would contact be dangerous? Or would you advise Palm Springs, Calif., which is also located in an arid area?

Irryng Friedman, M.D., Peekskill, N. Y.

ANSWER.—There would be no danger in having an 11½ year old boy live in Tucson, Ariz. His exposure to tuberculosis contact in the public school systems of Arizona would be no higher than it is in Peekskill, N. Y.

PILONIDAL CYST

PILONIDAL CYST

To the Editor:—In the October 18 issue of *The Journal*, p. 1404, there appeared a question entitled Pilonidal Cyst. The case cited concerns a recurrence of this lesion. Please permit me to call your attention to radiation therapy as an effective form of treatment for recurrent pilonidal cysts and sinuses (Turell, Robert: Radiation Therapy for Recurrent Sacrococcygeal Cysts and Sinuses, *Surgery* 8: 469 [Sept.] 1940). I have reported 4 cases of recurrent pilonidal sinuses that responded to therapy in doses of 600 to 900 roentgens. More recently, however, a larger dose of 1,200 to 2,100 roentgens has occasionally been employed. In the original paper I said "It is conceivable that, when all branches of the sinus or ectopic epithelium are incompletely removed during the original operation, radiation therapy may fail, and reoperation may become necessary." Radiation therapy was suggested mainly on the proposition that recurrence after operation is due primarily to incomplete extirpation of infected tissues. I feel that this form of therapy, based on subsequent personal experience and on that of several colleagues specializing in radiation therapy, is an effective substitute for operation for recurrence of infected pilonidal (sacrococcygeal) sinus. Reoperation, however, is indicated in cases in which branches of the cyst or sinus or ectopic epithelium were incompletely removed at the original operation.

USES AND LIMITATIONS OF ESTROGENS IN GYNECIC PRACTICE

E. C. HAMBLÉN, M.D.

DURHAM, N. C.

Estrogens constitute a diverse group of chemical compounds capable of producing estrous phenomena in experimental animals and reproduction in woman, to a great degree the physiologic functions which are attributed to the follicular hormone of her ovaries.

There are two general classes of estrogens: (1) those which are identical chemically with the steroids extracted from the ovaries, placentas or body fluids, i. e., hormones, and (2) those synthetic pharmacologically active agents which bear no structural chemical likeness to natural hormones.

All three of the estrogenic hormones—estrone, estriol and estradiol—have been extracted from woman's urine and are available commercially as free steroids or as esters. During the past three years estrogenic compounds derived from stilbene, particularly diethylstilbestrol and its esters, have been subjected to broad clinical investigations looking toward their release into commerce by the Food and Drug Administration.

The primary pharmacologic action of estrogens is on the genital system: endometrial, cervical and vaginal epithelium; myometrium; endometrial and myometrial vascular systems, and the parenchyma of the breasts. Secondary effects are produced in the skin and its appendages, the peripheral vascular bed and, perhaps, the osseous system. Reciprocities in function exist between estrogens, the anterior lobe of the pituitary gland, the adrenals and thyroid. No evidence has been submitted that estrogens stimulate ovarian function. There is good reason to believe, however, that they may depress this function by means of effects on the pituitary. These last two considerations qualify their therapeutic role as being a substitutional or complementary one rather than one which permits stimulation of hypofunctioning ovaries.

In general, the gynecic conditions in which estrogens have been employed on presumed rational indications are (1) substitutional or complementary therapy in those instances of adolescent or adult ovarian failure wherein the functional pathologic condition is intrinsic to the ovaries themselves; (2) in the treatment of local hypoplasias of the accessory sexual system; (3) as antagonistic therapy in hyperfunctional states of other glands, such as the pituitary or adrenals, and (4) for specific local effects on certain tissues, i. e., the vaginal epithelium, the estrogens being employed as pharmaco-

logic agents rather than as means of treating endocrine disease.

In these various therapeutic applications estrogens have been administered effectively by various routes: by mouth, intramuscularly, topically applied to the vaginal and the nasal mucosa, by dermal inunction and by the subfascial implantation of sterile pellets of compressed crystals of hormone. None of these methods permit, doubtlessly, an entirely efficient or economical duplication of normal physiologic levels of estrogenic function.

My purpose in this communication is a consideration of uses and limitations of estrogenic therapy in gynecology when based on the aforementioned and apparently rational indications.

ESTROGENIC THERAPY IN OVARIAN FAILURE

Diverse grades of ovarian failure result from numerous causes, some of which are intrinsic to the ovaries while others are related to primary aberrations in other glands or are due to strictly extra-endocrine causes. An ideal therapy would permit the salvage of both the germinal and the endocrine functions of ovaries, i. e. would induce or reinstitute normal fertile ovarian cycles. When there is resort to substitutional or complementary therapy with estrogens, the immediate result may be quite satisfactory from an endocrine point of view, but this therapy cannot substitute for the germinal failure of ovaries. Estrogenic therapy is rational only in hypovarianism due to intrinsic ovarian failure, such as that which results from surgical or roentgenologic damage, pelvic disease or tumors or sexual aging. Hypovarianism due to thyroid, adrenal or pituitary disease or resulting from constitutional impairment should be handled, if possible, by therapeutic attention to the primary cause rather than by substitutional therapy at the ovarian level. If apparent or real ovarian failure is related to inadequate endometrial function, complementary therapy with ovarian steroids may constitute a rational therapeutic approach.

When there exist severe grades of intrinsic ovarian failure, of either estrogenic or corpus luteum type, substitutional therapy with estrogens or with estrogens and progesterone, regardless of how dramatic the immediate endocrine responses are, has obvious limitations: 1. Complete substitution year after year for the endocrine functions of the ovaries, similar in kind to that necessary with thyroid substance for hypothyroidism or with insulin for diabetes mellitus, imposes a financial burden which few patients can assume. 2. If and when treatment is stopped, regressional alterations promptly follow which destroy for the most part the accomplishments of therapy; the combined use of estrogens and progesterone under these circumstances is said to lessen the regressions which follow withdrawal of therapy. 3. Despite most intensive therapy of this sort, patients remain sterile.

From the Endocrine Division of the Department of Obstetrics and Gynecology, Duke University School of Medicine and Duke Hospital.
Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

These aforementioned limitations delineate no clear-cut gynecic applications of prolonged substitutional therapy. Fortunately, ovarian deficiency rarely impairs health or somatic efficiency. The cosmetic inelegance of the young woman with well defined adolescent hypovarianism constitutes one of the few conditions, if not the only one, in which some attempt at limited employment of complete substitutional therapy seems indicated at present. The rationale of therapy in this condition is (1) to curb abnormal somatic overgrowth, common in these patients, by effecting epiphyseal closures, a therapeutic hope not established as yet as a fact; (2) to bring about some degree of sexual attractiveness of the patient, which accomplishment affords salutary psychic alterations, and (3) to produce genital growth and development in the hope that the ovaries may become capable of yielding full, normal responses to intrinsic pituitary influences or to those afforded by an adequate gonadotropic therapy.

The use of full substitutional doses of steroids for the sole purpose of regulating the cyclicity of uterine flowing is condemned as being meddlesome and unnecessary. Only when too prolonged or too frequent episodes of uterine bleeding produce a drain on the hemopoietic system is one justified in the employment of an empiric hemorrhagenic-hemostatic schedule of endocrine therapy. The effectiveness of a system of cyclic steroid therapy, embracing the use of estrogens and progesterone, in controlling menometrorrhagia of young women has been established. Any therapy which will permit symptomatic handling of excessive uterine bleeding of young women without impairing their fertility in the future is a valuable one. This fact, however, does not weaken the general statement that, at present, there is too much endocrine therapy of the menstrual cycle and too few attempts at rational endocrine assessments of patients.

In the physiologic hypo-ovarianism of the climacteric, therapy with estrogens is valuable at times in facilitating the hormonal adjustments of a minority of patients. The employment of dosages comparable to those used in complete substitutional therapy is unnecessary and actually harmful if therapy is prolonged. The continued use of these large doses of estrogens can and will delay, and otherwise complicate, the physiologic process of sexual aging. Our progress in geriatrics has not been such that attempts to delay old age are advisable. Troublesome menstrual irregularities and generalized edema due to disturbances in the metabolism of water and electrolytes may follow injudicious estrogenic therapy at this time. Overstimulation of the aging endometrium may enhance the incidence of carcinoma.

All therapy at the climacteric should be in line with the general therapeutic desideratum: to lessen, but not completely substitute for, the physiologic ovarian deficit of those women in whom the secondary hormonal adjustments are proceeding too slowly, i. e. palliative but not full replacement therapy. Estrogenic therapy should be limited in its duration to several months; dosages should be kept small and should be administered orally if possible; if patients have bleeding cycles, therapy should be calibrated with these cycles, estrogens being withdrawn during expected episodes of bleeding lest menstrual irregularities ensue.

Relatively low grades of estrogenic deficiency or moderate degrees of lowered endometrial receptivity may result in incomplete "priming" or vascularization of the endometrium, with the result that minimal or no progestational alterations occur. Such apparent inter-

current ovarian failure may be transformed eventually, owing to possible endometrial functions in steroid metabolism, into more real disturbances of ovarian function, i. e. corpus luteum failure. Some evidence has been presented that cyclic steroid therapy with estrogens and progesterone, or perhaps with estrogens alone, permits therapeutic salvage of patients with functional irregularities of uterine bleeding and endocrine sterility related to these etiologic factors. In these instances, therapy may be regarded as being complementary: ovarian function is complementary until such time that spontaneous adjustment can be made.

ESTROGENIC THERAPY OF LOCAL HYPOPLASIAS

Generalized hypoplasia of the sexual system is characteristic of severe estrogenic failure originating during adolescence and, likewise, distinct regressional alterations in the genital apparatus are associated with intercurrent estrogenic failure during the adult period. When, however, sexual hypoplasia is limited to a particular organ or organs, as the uterus or breasts, in women otherwise well feminized, it is found usually that the end organs and not the ovaries are at fault. Intensive estrogenic therapy designed to develop these hypoplastic organs is usually unsuccessful and may result in damage to intrinsic ovarian function. In a number of women who exhibited no evidence of ovarian deficiency except rudimentary uteri we have been unable to demonstrate any uterine enlargement from injections of estradiol benzoate or dipropionate in daily doses as large as 15,000 rat units for as long as three months. Similar experiences have occurred in the treatment of unilateral hypomastia with estrogenic ointments.

When, however, a patient with typical adolescent hypo-ovarianism is concerned chiefly by the cosmetic limitations imposed by the associated hypomastia, gratifying temporary results, and some permanent benefit due chiefly to massage, may be obtained from the local use of estrogenic ointments. This method of administration of estrogens permits concentrations of the dosage at the site of desired action. All the effects obtained from the inunction of estrogenic ointments are not local, however, as 1 of our cases illustrates:

A woman aged 24 years had the typical body build of well defined adolescent hypo-ovarianism and her uterus was of almost rudimentary proportions. She had never experienced uterine bleeding. The nightly inunction of a drachm (4 Gm.) of ointment containing 3,000 rat units of estradiol benzoate into the skin about each juvenile breast not only resulted in mammary hyperplasia but also, after three months of therapy, sufficient uterine hyperplasia had occurred to permit the patient's first episode of uterine bleeding.

ESTROGENIC THERAPY DESIGNED TO DEPRESS HYPERACTIVITY OF OTHER GLANDS

Theoretically, intensive estrogenic therapy should be of value in depressing hyperfunctional states of the anterior pituitary and in overriding virilizing effects produced by hyperactivity of the androgenic elements of the adrenal. While it is believed generally that large doses of estrogens are capable of depressing the moderate hyperactivity of the endocrinotropic influences of the pituitary which characterize climacteric failure of the ovaries, clinical experience has not found this therapy to be of any value in combating hyperpituitary gigantism or the symptoms and signs of pituitary basophilism. Likewise, estrogens have not been demonstrated to be effective in the treatment of hirsutism in general or as endocrine antagonists in virilizing syndromes arising from adrenal disease.

ESTROGENIC THERAPY FOR LOCAL VAGINAL
EFFECTS

Special epithelial effects of estrogens have been adapted to an effective therapy of gonorrheal vaginitis of childhood and to nonspecific postmenopausal vaginitis. In neither of these conditions is the indication for therapy a truly endocrine one, since the hypo-ovarianism and the atrophic state of the vaginal epithelium is normal at these physiologic epochs. Estrogens are used here similarly to any other pharmacologically active agents: their specific action is concerned with vaginal cornification and the production of vaginal acidity, both of which effects an increase in the resistance of the host to the infecting organisms. Dosages of estrogens employed in this therapy can and should be kept low enough to avoid general endocrine effects, such as premature adolescent phenomena in the child or the return of uterine bleeding in the climacteric woman. The fact that treatment is necessary for only six to eight weeks, as a rule, makes it practical and usually free from undesired side effects.

Some gynecologists have employed these vaginal effects of estrogens, usually locally applied, in the pre-operative preparation of postmenopausal women for vaginal procedures. It has been stated that the cornification, vaginal acidity and increased vascularity which result from this therapy have facilitated postoperative healing of the vaginal tissues.

EMPIRIC AND CONTRAPHYSIOLOGIC USES
OF ESTROGENS

A large amount of estrogenic therapy at present is founded only on the empiric association of certain symptoms with the presumed existence of significant ovarian failure. This type of therapeutics, if it employs potent agents in effective doses, is likely to oppose the intrinsic function of ovaries and to upset their hormonal reciprocities with other glands. Two practices in recent organotherapeutics which are employed somewhat widely illustrate what is meant by contraphysiologic usage.

Some workers report good results from intensive estrogenic therapy in instances of "menstrual migraine." Their plan of treatment is to circumvent these headaches by postponing or suppressing menstruation. To this end doses of from 10,000 to 15,000 rat units of estrogen are given daily for from three to four weeks or longer. Menstrual irregularities occur commonly through disturbances produced in the gonadopituitary reciprocities, which are temporary, however, unless therapy is continued for long periods of time.

Many of the recent studies of so-called "idiopathic" or "essential" dysmenorrhea accept the occurrence in this condition of fundamentally normal ovarian function. Some workers have advised the use of repeated injections of estrogens as large as 10,000 rat units every third day for from three to ten doses, beginning these at the end of flowing, to override or inhibit corpus luteum function; relief of dysmenorrhea has been correlated by them with such a contraphysiologic effect. They described the dysmenorrhea as returning, however, quite promptly with the cessation of therapy. This type of treatment seems neither practical nor rational.

SUMMARY AND CONCLUSIONS

Estrogens have a definite, though restricted, role in gynecic therapy. Full substitutional therapy for severe or complete ovarian failure permits striking endocrine responses but has little practical value, since

germinal failure (sterility) is not altered. When therapeutic schedules for estrogenic substitution or complementation are limited in scope and in proposed duration (adolescent ovarian failure and intercurrent episodes of relative ovarian failure producing some irregularities of bleeding and/or endocrine sterility), presently available estrogenic hormones, despite expense, permit practical applications. These hormones, likewise, permit worth while and not too expensive applications in the undesired symptomatology of certain climacteric women and in childhood and senile vaginitis.

Nonhormonal estrogens (of the diethylstilbestrol group), if released by the Food and Drug Administration, would circumvent only one of the therapeutic limitations of estrogens: their relative expense. Being orally active, cheap and highly potent, uncritical use of them by physicians and self medication with them by patients would add, doubtlessly, to an already widespread contraphysiologic and empiric estrogenic therapy.

ANDROGEN THERAPY IN GYNECOLOGY

SAMUEL H. GEIST, M.D.

AND

UDALL J. SALMON, M.D.

NEW YORK

Synthetic testis hormone (testosterone propionate) is being used with increasing frequency in the treatment of a number of functional gynecologic conditions. We have previously reported on its use in the treatment of the menopausal syndrome,¹ functional menometrorrhagia,² dysmenorrhea,³ premenstrual tension,⁴ pain of ovulation and endometriosis, and functional mastopathies.⁵ Our experience with androgens in gynecologic therapy, which extends over a period of more than four years and is based on a series of 422 cases, has convinced us that their use as therapeutic agents has a sound rationale and a well defined place in our endocrine armamentarium. However, like so many other valuable therapeutic agents, their use is not unattended by harmful potentialities unless specific indications are observed and appropriate safeguards employed. Fortunately, the range of biologic effects exerted by these hormones, the threshold of tolerance and the objective criteria for regulating the dosage have been clearly enough defined to warrant recommending their use in the treatment of selected types of gynecologic endocrine disorders.

Here we wish to present our observations of (a) the endocrinologic effects of administration of androgen to women; (b) the therapeutic properties of androgens; (c) the signs and symptoms of overdosage, and (d) the methods that can be used which make it possible to utilize the therapeutic properties of these hormones without inducing the undesirable virilization (arrhenomimetic) effects.

From the Gynecological Service of Dr. Geist and the Laboratories of the Mount Sinai Hospital.

Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

The following pharmaceutical houses supplied the androgens used in this study: Schering Corporation, Bloomfield, N. J., testosterone propionate (Oreton), methyl testosterone (Oreton-M), pregnenolone (Pranone) and Ciba Pharmaceutical Products, Inc., Summit, N. J., testosterone propionate (Perandren) and methyl testosterone (Metandren).

MATERIAL AND METHODS

This report is based on the observation of 422 patients who were treated with various androgens, namely testosterone propionate, ethinyl testosterone and methyl testosterone. These cases included normally menstruating women and those presenting a variety of gynecologic disorders, namely functional uterine bleeding, uterine fibromyomas associated with menorrhagia, dysmenorrhea, premenstrual tension, mastalgia, endometriosis and the menopausal syndrome.

METHODS OF ADMINISTRATION

The methods of administration in this series have been (a) intramuscular (testosterone propionate), (b) enteral (testosterone and methyl testosterone), (c) sublingual absorption (testosterone in propylene glycol) and (d) subcutaneous implantation (crystals and pellets of testosterone and testosterone propionate).

Although preliminary investigations were performed with a number of androgens, only three (testosterone, testosterone propionate and methyl testosterone) were found to be sufficiently potent to be effective. Of these, testosterone propionate was found to be the most potent when administered intramuscularly or subcutaneously. The majority of our studies were performed with this compound.

ENDOCRINOLOGIC EFFECTS OF TESTOSTERONE
PROPIONATE IN WOMEN

In our attempt to determine the biologic properties of testosterone propionate, the doses were varied widely. Patients were given individual doses varying from 5 to 100 mg. for periods varying from two weeks to eight months. Total doses ranged from 60 to 3,200 mg. Of the 422 patients in this series, 245 received 300 mg. or less, 85 received doses ranging from 300 to 600 mg. and 92 received from 600 to 3,200 mg. It soon became apparent that the biologic effects induced by testosterone propionate varied, depending on the dosage administered and on the time of the menstrual cycle during which the hormone was given.

Effect of 500 Mg. or More of Testosterone Propionate per Cycle.—Doses of 500 mg. or more per cycle cause (a) inhibition of the gonadotropic hormone activity of the hypophysis;¹ (b) suppression of follicular growth, ovulation and corpus luteum formation;² (c) inhibition of the formation of estrogen and progesterone and excretion of pregnandiol;⁷ (d) suppression of menstruation;⁸ (e) abolition of the normal cyclic endometrial patterns leading to endometrial hypoplasia or atrophy;⁹ (f) involutional changes in the vaginal mucous membrane characteristic of deprivation of estrogens;¹⁰ and (g) virilization phenomena, namely hair growth on the face, extremities and occasionally on the lower part of the abdomen, deepening of the voice and, in some cases, enlargement of the clitoris.

Effect of 300 Mg. or Less per Cycle.—When testosterone propionate is administered in doses of 300 mg. or less during one cycle (approximately twenty-eight days), the inhibitory effects do not usually occur. Men-

struation is not suppressed and the endometrium usually reveals no regressive changes in the microscopic pattern, indicating that the follicular phenomena in the ovary (ovulation and estrogen and progesterone formation) have not been inhibited. The 500 mg. dose per cycle appears to be the approximate threshold for suppressive effects, providing the total dose is distributed during the entire cycle or given during the first ten days of the cycle before the hypophysis has secreted gonadotropin for the current cycle or before the gonadotropin has been able to exert its action on the ovary. Similar amounts of hormone administered during the latter half of the cycle do not suppress the following menstrual period. Experimental studies indicate that the suppressive action of the hormone is achieved by inhibition of the gonadotropic activity of the hypophysis with consequent suppression of ovulation and production of estrogen and progesterone by the ovary.¹¹ It becomes understandable, therefore, why an amount of hormone which is suppressive (500 mg.) during the first two weeks of the cycle (before ovulation has occurred) has no such inhibitory effect on the current menstrual phenomena if administered during the last two weeks of the cycle. It has been found, furthermore, that one can produce the same suppression of menstruation by concentrating a massive dose (approximately 1,000 mg.) during the first five or six days of the cycle.

RELATION OF DOSAGE TO ARRHENOMIMETIC
PHENOMENA

Experimentation with various doses of testosterone propionate revealed the fact that, if menstruation is suppressed by the hormone, patients are likely to notice some hypertrichosis, deepening of the voice and some enlargement of the clitoris. These phenomena have been observed by a number of investigators.¹² Our studies have shown that there is a fairly well defined dosage threshold for these phenomena which, for the average woman, is approximately 500 mg. of testosterone propionate a month. When this monthly dose is exceeded, the incidence of arrhenomimetic phenomena is approximately 21 per cent. Below this dosage level, the incidence of arrhenomimetic effects drops rapidly. When administered in doses of from 250 to 300 mg. a month, the incidence is approximately 1 per cent. Smaller doses (from 50 to 250 mg. a month), in a series of 179 cases, produced none of these arrhenomimetic effects.

THERAPEUTIC PROPERTIES OF TESTOSTERONE
PROPIONATE

A review of the endocrinologic effects resulting from the administration of androgens to cyclic women makes it become clear that there is available in testosterone propionate a substance which has powerful suppressive effects on the entire female endocrine system and, by virtue of this, great therapeutic potentialities. A fact of great significance, which adds to its value as a therapeutic agent, is the range of gradations of biologic effects which appear to be dependent on quantitations of dosage. Thus it has been established that the threshold for suppression of the gonadotropic activity of the hypophysis, with its consequent inhibitory action on

the ovary and its hormone production, is approximately from 500 to 600 mg., administered during one cycle. The administration of androgens in excess of this amount results in the elicitation of arrhenomimetic phenomena, whereas smaller amounts (less than 250 mg.) cause neither suppressive nor arrhenomimetic effects. It is obvious that, to be of any practical value, androgens would have to exercise their therapeutic properties below the threshold for arrhenomimetic effects. Fortunately, this happens to be the case. Although during the course of our studies patients have been given doses in excess of 500 mg., and some as much as 1,800 mg. a month, with consequent development of hirsuties, voice changes and acne, this occurred before the threshold level for arrhenomimetic phenomena was clearly determined. Since then it has been our practice to keep the dosage below this level, and we were gratified to find that androgens have a therapeutic action in doses which are considerably below the threshold for arrhenomimetic phenomena.

ABNORMAL UTERINE BLEEDING

In the past three years several investigators have reported good therapeutic results in functional bleeding obtained with testosterone propionate.¹³ We reported a series of 25 cases in 1938¹⁴ and an augmented series, totaling 45 cases, in 1940.¹⁵ The results in these cases were, on the whole, good as regards the control of the bleeding. Because of the fact that in a number of those cases large doses (350 to 1,000 mg. a month) were given, arrhenomimetic effects developed. In spite of the fact that the hypertrichosis and voice changes subsequently disappeared, the occurrence of these side effects is a serious objection to the use of androgens in gynecology. Fortunately, subsequent studies revealed the fact that functional menorrhagia could be controlled, in the majority of instances, with doses of testosterone propionate which are below the threshold for arrhenomimetic effects.

TABLE 1.—Results in Thirty-Three Cases of Functional Bleeding with Subarrhenomimetic Doses of Testosterone Propionate (150 to 250 Mg. a Month)

	Cases	Percentage
Primary results in 33 cases (during initial course of therapy)		
Normal menses	25	76
Moderate improvement	5	15
Failures	3	9
Late results in 30 cases		
Good therapeutic results without further treatment (periods of observation from 6 months to 3½ years).....	60	
Normal menses	15 cases, 50%	
Hypomenorrhea	2 cases, 7%	
Amenorrhea	1 case, 3%	
Moderate recurrence, 8 cases (within 3 to 6 months) (subsequently controlled with supplementary androgen therapy)	27	
Complete recurrence, 4 cases (within 3 to 6 months).....	13	

The clinical results obtained in the series of cases with doses below the arrhenomimetic threshold are shown in table 1. In the majority of the latter group doses not exceeding 250 mg. a month were given. The primary as well as the later therapeutic results with this

dosage are not quite as good as those obtained by us with larger doses.² Thus, there were only 6.6 per cent failures in a series of 45 cases, in the majority of which the larger doses were given, in contrast to 9 per cent failures and 13 per cent recurrences in the series of 33 cases in which the smaller (subarrhenomimetic) doses

TABLE 2.—Results in Twenty-One Cases of Uterine Bleeding Associated with Fibroids

	Cases	Percentage
Primary results		
Good therapeutic results.....	15	71
Moderate improvement	4	19
Failures	2	10
Late results (follow-up, 3 mo. to 4 yr. in 19 cases)		
Normal menses	7	37
Moderate recurrence (controlled with supplementary androgen therapy).....	4	21
Complete recurrence	8	42
(9 of these were subsequently operated on: 7 were found to have submucous fibroids; 2, adenomyosis)		

were given. The lower percentage of satisfactory therapeutic results obtained with the smaller doses is more than compensated for, however, by the absence of arrhenomimetic effects in these series.

Menometrorrhagia Associated with Fibroids.—The results in this series were not as satisfactory as in the functional group. The primary results were good in the majority; that is, while the patients were receiving the androgen therapy, or for a month thereafter, bleeding was either completely suppressed or was less copious and of shorter duration. Discontinuation of the androgens was followed by complete recurrence of severe bleeding in 48 per cent. The majority of these patients were subsequently found to have either submucous myomas or adenomyosis. Four patients with uterine fibroids (in whom hysterectomy was contraindicated because of cardiovascular disease) have been satisfactorily controlled with small doses of testosterone propionate and methyl testosterone for more than three years.

Limitations of Androgens in the Treatment of Menometrorrhagia.—The value of androgen therapy in the treatment of abnormal uterine bleeding has become more clearly defined since we have had the opportunity of studying its effects in a large series of cases and over a longer period of time. It is quite clear now that this therapy is most effective in the functional type of menorrhagia or menometrorrhagia occurring in women at the premenopausal age. Occasionally in such patients amenorrhea develops which may last for as long as six months or appear to be permanent. In younger women the results are somewhat less satisfactory, recurrence being more frequent. We have found it advisable to forestall recurrences by continuing androgen therapy in small doses for a period of several months after the establishment of normal menstruation. Usually 10 mg. of testosterone propionate, once or twice a week, is sufficient. We have found that oral (methyl testosterone) or sublingual (testosterone propionate in propylene glycol solution) administration serves satisfactorily as supplementary therapy. It is worth remembering that androgens have no cumulative effects as regards the arrhenomimetic phenomena. Apparently, if the hormone is given in small doses (e. g. from 10 to 20 mg. of testosterone propionate weekly, or from 5 to 10 mg. of methyl testosterone daily), it produces none of these effects even if it is continued for many

Geist, Salmon, and Gaines.²⁴ Salmon, Geist, Gaines and Walter.¹⁵ Mazer and Mazer.¹² Huffman.²³ 14. Geist, S. H.; Salmon, U. J., and Gaines, J. A.: Endocrinology 23: 784, 1938. 15. Salmon, U. J.; Geist, S. H.; Gaines, J. A., and Walter, R. I.: Am. J. Obst. & Gynec. 41: 991, 1941.

months. Some of the patients have received these small doses for periods of from six to sixteen months, totaling as much as 930 mg. of testosterone propionate and more than 2,000 mg. of methyl testosterone, without any arrhenomimetic effects or acne.

At this point, we think it important to point out that, although we believe that androgen therapy is effective in certain types of abnormal bleeding, one should not begin androgen therapy before definitely excluding neoplastic disease. It has been our practice to do either an endometrial biopsy or curettage in all cases prior to treatment.

FUNCTIONAL DYSMENORRHEA

Limitations of space do not permit a review of the theories of the etiology of functional dysmenorrhea.

The crux of the problem appears to lie in the fact that dysmenorrhea is not a clinicopathologic entity but rather a symptom complex which may be caused by a number of apparently unrelated factors, acting separately or in combination. In some cases, mechanical factors or intrauterine disease (adenomyosis), may be responsible for the symptoms. Furthermore, it is difficult to evaluate the role played by psychic factors both with regard to the causation of the symptoms and their amelioration. This probably accounts for the wide variety of therapeutic agents that have been found efficacious in the hands of different observers. . . . From all the evidence available, it seems that functional dysmenorrhea is caused by a disturbance in myometrial function which, in all probability, is the result of a lack of integration of the various hormonal factors that normally produce rhythmic painless contractions. Whether this is due to excessive estrogen and/or progesterone stimulation or to a disturbance of their physiologic interrelations, is, at present, not clear. But as a basis for understanding the therapeutic action of testosterone, it is sufficient if we accept the hypothesis that it is some aberration of gynecogen action on the myometrium that is the cause of functional dysmenorrhea. It has been shown that testosterone completely suppresses the contractions of the fallopian tubes¹⁶ and uterus.¹⁷ In smaller doses its suppressive effect is less intense and it probably reduces the excessive and abnormal uterine contractions to a physiologic pattern. Whether testosterone propionate accomplishes this by depressing the reactivity of the myometrium or by modifying or reducing the stimulating action of the estrogens remains, for the present, unknown.⁷

Dosage.—During the experimental stage of our study we treated dysmenorrhea patients with doses varying from 50 to 900 mg. a month, the total dosage varying from 100 to 1,500 mg. In our first series of 30 patients, reported in 1938,³ the majority of the patients received more than 300 mg. a month; several received more than 600 mg. in one month. As a result of the high dosage employed, a number of characteristic arrhenomimetic effects developed. Since then, we have reduced the dosage below the arrhenomimetic threshold and have found that quite satisfactory therapeutic results can be obtained with doses not exceeding 250 mg. a month. Twenty-five mg. twice a week for the duration of one cycle was found sufficient in most instances. It is important not to discontinue the therapy completely as soon as the symptoms are relieved. The dose should be progressively reduced by approximately 25 per cent each month.

Results.—In the series of 30 cases reported in 1938³ there were 4 complete failures and in 4 only partial improvement; 22 cases, or 73 per cent, showed good

primary results. Since then 25 more cases have come under treatment (with doses not exceeding 250 mg. a month), with essentially similar results (table 3). In 18 there was complete relief while under therapy; 4 showed considerable improvement and 3 no improvement. Of the 22 primary successes, 14 were kept on maintenance therapy for from two to three months after the initial course of treatment. This consisted, in the majority, of from 10 to 20 mg. of methyl testosterone, taken by mouth, for fourteen consecutive days, beginning on the twelfth day of the cycle. Twelve of these remained symptom free for periods varying from six to twenty months after discontinuation of the methyl testosterone. In 2 some recurrence of symptoms developed within three months after the methyl testosterone was stopped, with prompt relief after the medication was resumed.

In 8 of the cases with good primary results supplementary androgen therapy was not given. Of these, 5 remained symptom free for the period of observation, which varied from four to sixteen months. In 1 there

TABLE 3.—Results of Treatment in Twenty-Five Cases of Functional Dysmenorrhea with Subarrhenomimetic Doses of Testosterone Propionate

	Cases	Percentage
Primary results		
Completely relieved	18	72
Considerably improved	4	16
Not improved	3	12
Late results in 22 cases with satisfactory primary results (4 to 20 months follow-up)		
(A) 14 with supplementary oral therapy (methyl testosterone) for 2 to 3 months		
12 symptom free for 6 to 20 months after discontinuation of oral therapy		
2 moderate recurrences within 3 months after discontinuation of oral therapy		
(B) 8 without supplementary therapy		
5 symptom free for 4 to 16 months		
1 moderate recurrence after 4 months		
2 complete recurrences within 3 months		

was a moderate recurrence after four months; in 2, complete recurrence within three months after cessation of therapy. One of the latter was satisfactorily controlled with methyl testosterone. Further therapy was not attempted in the other because of an antecedent acne which seemed to be aggravated by the androgens. This case subsequently showed moderate improvement with ethinyl testosterone (pregneninolone).

The recurrence of symptoms after discontinuation of the androgen and their prompt control with the resumption of androgen therapy suggests a replacement phenomenon. Of the 3 patients who were not improved, 2 had hypoplastic uteri and were subsequently treated with estrogens, with complete relief of the dysmenorrhea. The third had chronic adnexitis.

LIMITATIONS OF ANDROGEN THERAPY

The 4 failures in the first series of 30 cases and the 3 in the present series of 25 cases indicate the limitations of androgen therapy. Apparently, in the presence of endometriosis or chronic pelvic inflammatory disease, androgens have little effect in relieving the dysmenorrhea unless used in suppressive doses. The 2 cases of hypoplastic uteri which failed to respond to androgens but were relieved by estrogens point clearly to the advisability of giving estrogens from the beginning in such cases. The finding of a hypoplastic uterus in a patient complaining of dysmenorrhea should contraindicate the use of androgens.

It is worthy of note that none of the patients in this series showed hypertrichosis, changes in voice or enlargement of the clitoris.

PREMENSTRUAL TENSION

Premenstrual tension was first described by Frank¹⁸ and attributed by him to hyperestrinemia with low excretion of estrogen. It has been suggested that the syndrome is the result of overstimulation of the autonomic nervous system by the gynecogens, namely the estrogens and/or progesterone.¹⁹ On the basis of this theory, androgens have been used with gratifying results.²⁰ The emotional manifestations of this syndrome and the consequent difficulty of evaluating the role of psychogenic factors in the etiology of the disorder make it almost impossible to estimate the efficacy of the hormone therapy per se. However, the results of androgen therapy are so much more striking and uniform than other forms of treatment that we are inclined to the view that the relief of the symptoms is attributable to the androgens and not to incidental psychotherapy. Furthermore, 2 patients who were relieved with testosterone propionate were subsequently given, without their knowledge, progesterone for two consecutive cycles and, in both instances, the symptoms recurred.

Dosage.—We have found that 25 mg. twice a week, beginning on the twelfth day of the cycle and continued up to the next period, is sufficient in the majority of cases. Cases of severe involvement may require 25 mg. three times a week. The same course should be repeated for two additional cycles. Thereafter, the dose can be reduced to 10 mg. of testosterone propionate, twice a week, or 10 mg. of methyl testosterone a day for several cycles.

PREMENSTRUAL MASTOPATHIES

The premenstrual engorgement of the breasts which occurs normally in women has been shown to be caused by the stimulative effect of estrogens and progesterone on the epithelial elements of the acini and duct, as well as on the vascular elements.²¹ When these phenomena become exaggerated, the result is extremely painful and tender breasts and nipples, frequently associated with tender "lumps." These clinical manifestations of hypergynecogen stimulation should respond to the antigynecogen property of androgens. The effectiveness of androgen therapy has been attested by the reports of several investigators. Good therapeutic results were first reported by Desmarest and Capitain²² and have since been confirmed by others.²³

Dosage.—Twenty-five mg. of testosterone propionate, twice a week, beginning on the twelfth day of the cycle and continued for two cycles, is usually adequate. Supplementary therapy with methyl testosterone (10 mg. daily, beginning on the twelfth day of the cycle) is recommended for several months after the discontinuation of the parenteral therapy.

POSTPARTUM PAINFUL ENGORGEMENT OF THE BREASTS

In women who do not wish to nurse, these unpleasant symptoms can be prevented by the postpartum administration of testosterone propionate.²⁴ We have obtained satisfactory results by administering 50 mg. of testosterone propionate intramuscularly within a few hours after delivery and 50 mg. daily for two days thereafter. One of us (U. J. S.) had the occasion to note recently, in 2 patients who decided to nurse their babies on the third and fourth days after they had received 150 and 250 mg. respectively, that, although the breasts were not tender or engorged, the patients were able to lactate adequately. We have found methyl testosterone, given orally, in doses of 60 mg. daily for four days as effective as testosterone propionate.

ENDOMETRIOSIS

The rationale for this treatment is based on the fact that the progress of the disease is predicated on the growth-stimulating effects of estrogens and progesterone on the ectopic endometrial tissue. Androgens have, therefore, been recommended in the treatment of the early stages of the disease and postoperatively in those cases in which the ovarian tissue is preserved because of the importance of conserving the reproductive function.⁷ This therapy is manifestly not practical during the advanced stages of the disease. To be of any value, the hormone must be administered in suppressive doses and, in view of the fact that this approaches very closely the threshold for arrhenomimetic phenomena, the dosage should be carefully controlled with vaginal smears.

MENOPAUSE

The first report of the clinical use of androgens in the treatment of the menopausal syndrome was made by Mocquot and Moricard,²⁵ who described slight improvement in the flushes (with as little as a single injection of 5 mg.) but noted intensification of the nervous instability. It has been shown¹ that by administration of large doses of testosterone propionate (815 mg.), the gonadotropic hyperactivity of the hypophysis in a surgical castrate can be inhibited and the symptoms relieved. These clinical and hormonologic observations have since been confirmed.²⁶

Unfortunately, the impression has been created by several clinical reports that testosterone propionate is as effective as estrogen in the treatment of the menopausal syndrome. This is not in agreement with our observations. It is true that in large doses (from 100 to 200 mg. a week, for several weeks), testosterone propionate has an estromimetic effect and can relieve the menopausal symptoms in a considerable number of cases. This is, however, a slow and expensive method of achieving a therapeutic effect which can be obtained more rapidly, completely and inexpensively with estrogens. There are, however, three groups of patients in whom androgen therapy is indicated for the menopausal syndrome: These are patients with menopausal symptoms who are still menstruating or have menorrhagia or metrorrhagia. Administration of estrogens to such

patients not infrequently results in aggravation of the bleeding.⁷ The second group consists of patients in whom the symptoms are only partially relieved by estrogens. These patients frequently respond to small doses of androgens (from 10 to 25 mg. a week) as a supplement to the estrogens.⁷ A third group consists of postmenopausal patients who are distressed by the uterine bleeding resulting from estrogen therapy. In these patients, we have found that the combining of androgens with estrogens is effective in controlling the symptoms without inducing bleeding. The optimal ratio varies somewhat in different women. We have found that in the majority of these patients a ratio of estradiol to testosterone of 1:10 by weight (given parenterally) is satisfactory. We have found the vaginal smear useful as a guide in adjusting the ratio to individual needs.

VALUE OF VAGINAL SMEARS IN REGULATING ANDROGEN DOSAGE

During the course of our studies it was observed that the vaginal smears would frequently reveal signs of estrogen deficiency before any clinical evidence of overdosage was noted.²⁷ Making use of this observation, we have found it of value to take vaginal smears each week during the course of the androgen therapy. With the fuchsin stain²⁸ a smear can be stained and read in a few minutes. At the first sign of effect from the androgen in the vaginal smears, androgen therapy should be discontinued.

METHYL TESTOSTERONE

Methyl testosterone has been found to be a therapeutically effective androgen when administered by the oral route. Its biologic and therapeutic properties are similar to those of testosterone propionate.⁷ Per unit of weight, it appears to be approximately one third to one half as effective by mouth as testosterone propionate is when administered parenterally. This compound is absorbed also in effective amounts when administered by inunction to the skin, but this method of therapy is unsatisfactory because of the difficulty in controlling the dose and the annoyance to the patient.

SUBLINGUAL ABSORPTION OF TESTOSTERONE IN PROPYLENE GLYCOL SOLUTION

We have found that estradiol²⁹ and testosterone¹⁵ are absorbed in therapeutically effective amounts if administered sublingually in solution in propylene glycol. The androgen solution contains 25 mg. of testosterone per cubic centimeter of propylene glycol. In order to insure absorption of the hormone, the drops are instilled under the tongue and the patient is instructed not to swallow for five minutes. Preliminary studies have shown that this is an economical method of administering androgens. It is still, however, in an experimental stage.

IMPLANTATION OF CRYSTALS AND PELLETS OF TESTOSTERONE AND TESTOSTERONE PROPIONATE

Loeser³⁰ has reported satisfactory therapeutic results in 6 patients with menometrorrhagia (5 with fibroids; 1 with functional menometrorrhagia) and 2 with chronic cystic mastitis who were given implantations of testos-

terone and testosterone propionate. During the past three years, we have implanted crystals and pellets of testosterone and testosterone propionate in more than 40 patients in weights varying from 50 to 675 mg. We have found this method of administration of androgen of little value for clinical purposes. While there is no doubt that androgens administered by implantation are therapeutically effective, a number of the patients had arrhenomimetic symptoms within a few weeks, necessitating the excision of the pellets. In view of the proved effectiveness of parenteral and enteral administration of androgen and because of the importance of being able to vary the dose in accordance with the patient's response so that the maximum therapeutic effect is obtained without inducing the arrhenomimetic effects, it seems to us that there is hardly any justification for the implantation of androgen.

ETHINYL TESTOSTERONE (PREGNENINOLONE)

Ethinyl testosterone, which is closely related chemically to both progesterone and testosterone, possesses a unique variety of biologic properties. In animals, it has a progestomimetic, some estromimetic and very slight andromimetic action.³¹ It is, furthermore, active when administered orally.

In a series of 28 cyclic women, treated orally with doses varying from 30 to 60 mg. a day over periods of from one to three months, none of the suppressive effects which can be so strikingly produced with testosterone propionate and methyl testosterone were observed. Menstruation was never suppressed and no estrogen deficiency phenomena appeared. Furthermore, in no instance did virilization phenomena develop.³²

When administered orally to postmenopausal women, after adequate priming with estrogens, gestational changes were produced with doses of from 300 to 600 mg., administered over periods of from one to two weeks.³³

In ethinyl testosterone there is available an orally active substance which has a progesterone-like action. We have found it helpful in some cases of dysmenorrhea and premenstrual tension.⁷ It has proved ineffective, in our hands, in controlling functional menometrorrhagia.³⁴ Because of its progestomimetic action, this compound has been recommended in the treatment of threatened abortion.³⁵ Owing to the difficulty of evaluating its effectiveness, the use of ethinyl testosterone in this condition must still be considered as experimental.

COMMENT

The therapeutic effectiveness of androgens appears to stem from the ability (a) to inhibit the gonadotropic activity of the hypophysis, (b) to suppress or decrease estrogen production, (c) to nullify or modify the activity of the gynecogens, (d) to inhibit the proliferative processes in the endometrium and (e) to inhibit the reactivity of the uterine musculature.

As one reviews the complex biologic properties of testosterone propionate one cannot avoid the implication that, in the normal human female, endogenous androgens may have a somewhat similar function to perform.

There are a number of observations that support the theory that androgens play a physiologic role in the sex hormone organization of the human female. It has been shown that adult women excrete significant amounts of androgens³⁶ which are chemically identical with the androgens excreted by males, whereas the excretion of androgens before puberty and in old age is extremely small.³⁷ It may be inferred therefrom that androgens play some physiologic role in the sex hormone metabolism associated with menstruation. The demonstrated antigynecogenic properties of androgens in cyclic women and their therapeutic effectiveness in women presenting symptoms attributable to excessive or abnormal gynecogenic stimulation suggest that in normal women androgens have an antigynecogenic function; that normally the androgens and estrogens balance each other; that in certain gynecologic disorders the androgenic influence is defective or deficient (e. g., functional menorrhagia, dysmenorrhea, premenstrual tension) and that in others (e. g., amenorrhea, hypertrichosis) the androgenic influence is dominant. In the light of this theory, the use of androgens in gynecology can be considered as rational substitution therapy.

SUMMARY AND CONCLUSIONS

1. Four hundred and twenty-two women were treated with androgens during a period of five years.

2. Therapeutic effectiveness of androgens stems from their ability (a) to nullify or modify the action of estrogens, (b) to suppress or decrease the production of estrogens by the ovary, (c) to inhibit the proliferative processes in the endometrium, (d) to inhibit the reactivity of the uterine musculature and (e) to inhibit the gonadotropic activity of the hypophysis.

3. Doses of 500 mg. or more a month have a suppressing gonadotropin production by the hypophysis, follicle growth and ovulation, and estrogen and progesterone formation, inducing involutional changes in the endometrium and vaginal mucosa. Doses of this magnitude may induce acne and arrhenomimetic effects, namely hypertrichosis, deepening of the voice and slight enlargement of the clitoris.

4. Androgens exert their therapeutic effects in subarrhenomimetic doses, namely less than 300 mg. a month.

5. Androgens have been found effective in the treatment of (a) functional menometrorrhagia, (b) functional dysmenorrhea, (c) premenstrual tension, (d) premenstrual mastopathies, (e) postpartum engorgement of the breasts and (f) certain types of the menopause syndrome.

6. Androgen therapy has been found of value in less than 50 per cent of the cases in which menometrorrhagia was associated with uterine fibroids. Androgens appear to be of no value if the abnormal bleeding is attributable to submucous myomas.

7. An orally effective androgen is available in the form of methyl testosterone. Testosterone has also been shown to be absorbed in effective amounts when administered sublingually in solution in propylene glycol.

8. Pellet implantations of androgens have been found to be therapeutically effective, but they are not recommended for clinical use because of the greater advantages of parenteral and oral therapy.

9. In the doses recommended, the danger of arrhenomimetic effects (hypertrichosis, deepening of the voice, enlargement of the clitoris) resulting from androgen therapy is practically negligible.

10. A theory is formulated of the physiologic role played by androgens in the sex-endocrine balance of the normal female. In the light of this theory, functional menorrhagia, dysmenorrhea and premenstrual tension may be regarded as manifestations of a disturbance of the androgen-gynecogen balance resulting in an abnormal dominance of the gynecogens. Administration of androgens, in order to restore the normal balance, would, accordingly, appear to be rational therapy.

100 East Seventy-Fourth Street—875 Fifth Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. HAMBLÉN AND DRS.
GEIST AND SALMON

DR. CHARLES MAZER, Philadelphia: Dr. Geist and his associates attempt to formulate a theory as the basis for the marvelous results they obtained with the use of androgens in dysfunctional uterine bleeding, dysmenorrhea and premenstrual tension. They theorize that these three and almost all other dysfunctional gynecologic manifestations are due to a physiologic imbalance in the production of gynecogens and androgens. If this theory was correct, how could substitutive or complementary treatment with androgens relieve permanently so many of the patients? That androgens nullify or modify the activity of the gynecogens on the endometrium is evident from their ability to prevent estrogen-withdrawal bleeding in the castrated Rhesus monkey and human being. This local effect can be obtained in at least 50 per cent of menometrorrhagias of the dysfunctional type with the use of small doses of testosterone propionate, such as a total of 50 to 200 mg. There is, therefore, no need for the use of the large doses which inhibit, though temporarily, the pituitary ovarian mechanism and which are, moreover, too costly for the average patient. Even the smaller doses have, in my experience, evoked temporary masculinizing phenomena in 6 per cent of patients under 40 years of age. How distressing is even slight hypertrichosis to women at any age is well known. Fortunately, dysfunctional uterine bleeding occurring at this age can usually be controlled by other therapeutic measures which are less costly and less likely to produce undesirable by-effects. For these reasons it seems desirable to restrict, except in rare instances, the use of androgens to the premenopausal type of dysfunctional uterine bleeding wherein chorionic gonadotropin and other nonsurgical therapeutic agents are more or less ineffective. Premenopausal dysfunctional uterine bleeding, moreover, occurs at an age when suppression of the menstrual function merely hastens the inevitable and when temporary facial hairiness and hoarseness of the voice are more likely to be overlooked. In my experience both dysmenorrhea and premenstrual tension failed to respond to any appreciable degree to the administration of androgens in total doses of 50 to 200 mg. The remarkable results obtained by the authors with the use of the larger doses are noteworthy. Nevertheless, we must ponder whether these young women would not prefer their ailments to the risk of masculinizing effects, even if there were no other means of relieving their symptoms. The limited indications for estrogen therapy, as outlined by Dr. Hamblén, can be heartily endorsed. The substance has no peer in the realm

of pharmacology for relief of severe menopausal symptoms, if the dosage is initially adequate in quantity and frequency of administration.

Dr. LUDWIG A. EMGE, San Francisco: The authors have discussed the relative merits of *diametrically opposed methods* of treatment of the disturbances of the female sex organs. Dr. Hamblen's topic deals with a method of treatment which has experienced the test of time and therefore can be more readily evaluated than that discussed by Drs. Geist and Salmon. There is no doubt in my mind that estrogenic therapy has an important place in therapeutics. There is, however, grave doubt that it will keep this place unless its use is rigidly governed by physiologic principles. This can be achieved only if the doctor will make an effort to learn to understand the pharmacologic as well as the chemical nature of estrogenic substances, relying more on his own efforts of observation and deduction than on those enthusiastic detail men. The estrogens essentially are of substitutional value. They do not stimulate the ovaries nor do they make better ovaries, and they are not a panacea for all the ills of womankind. All you can expect of them is to take over at least temporarily the duties of the follicular apparatus. They will not correct any progressive deterioration of ovarian function. Their action is purely substitutional as far as we know today. Withdrawal of treatment permits the return of deficiency phenomena; hence their use in the menopause warrants careful study. If, during the period of substitution, other endocrine glands resume a more normal function, resulting in improvement of the general physical state of a woman, it still does not mean that this becomes a permanent state. It therefore is imperative that the use of these substances is regulated by an intelligent application of physiologic principles. Any deviation from this rule debases this therapy to the level of quackery. There is no doubt that ovaries can be damaged, nor is there any doubt that other endocrines can be seriously disturbed. I agree with Dr. Hamblen that the usefulness of estrogens is limited and their use as tonics neither necessary nor economic. Drs. Geist and Salmon have acquainted you with a new therapeutic agent applicable essentially to the same group of disturbances discussed by Dr. Hamblen. Physiologically, the androgens oppose the estrogens and hence promise to be of great value when the action of the natural estrogens is out of control. Drs. Geist and Salmon's large series of observations strongly supports this assumption, and my own observations point in the same direction. However, I feel that the usefulness of the androgens also is limited. Time and usage are necessary to permit proper evaluation of these substances.

Dr. JEAN PAUL PRATT, Detroit: The presentations by Drs. Geist and Salmon and by Dr. Hamblen represent two phases in the evolution of endocrine gynecology: the former, a period of experimental activity; the latter, a critical summary of previous experiments. The use of gonad materials to stimulate sex function goes back to antiquity. In 1849 the science of endocrinology began when Berthold demonstrated normal masculine development of castrated cocks by testicular grafts. In 1889 Brown-Séquard claimed sensational effects from testicular extracts administered to himself. In 1918 Pezard demonstrated development of the comb in capons by the injection of saline extracts of swine testes. Since 1927, when the first active principle of testes was isolated in Koch's laboratory, the field has widened rapidly. Androgens have been extracted from testes of animals and human urine. The chemical structure has been determined. Testosterone has been synthesized from cholesterol. Various compounds of the androgens have been prepared for experimental and clinical application. The effects in different species and in the human being have been compared. The effects at different ages and stages of development in both sexes have been studied. Today, Drs. Geist and Salmon have contributed an excellent comparison of several compounds. Many questions remain to be answered: What is the manner of action of the androgens? How are they utilized in the body? What is the effect on other endocrine glands and the whole organism? Why are androgens excreted in human urine but not in the urine of animals studied? What is the source of androgen in the female? It would seem that, with so many unanswered questions

the study of androgens must be regarded as still in the experimental phase. Dr. Hamblen, in discussing the uses and limitation of estrogens in gynecic practice, is dealing with a much later phase in the evolution of endocrine gynecology. The estrogens have been widely used for many years. By the method of trial and error their limitations are now quite well defined. The story of ovarian therapy begins in 1898 with the assumption of Prenant that the corpus luteum looked like a gland of internal secretion. Therapy has run through the gamut of transplants, desiccated ovary, whole ovary, ovarian residue, all sorts of extracts to chemically pure sterols and finally to diethylstilbestrol, which is chemically unrelated to the estrogens but which has estrogenic action. The literature of the last four decades is replete with reports of successful therapy with each and all the numerous ovarian preparations. The success has been too often proportional to the enthusiasm of the patient and the doctor.

Dr. JAMES B. HAMILTON, New Haven, Conn.: Male hormone substances (androgens) evoke definite responses in the female, and some of these actions have given rise to trial of their usefulness in gynecology. The problem at the moment, though, does not seem to be whether or not androgens evoke certain effects but whether they are the method of choice in management. That is a problem for the gynecologist. My associates and I have been studying the male eunuch and eunuchoid, particularly suitable subjects for study. They receive large doses for long-continued periods, as our desire is that which in the female would be excessive masculinization. With the use of these dosages in men previously lacking in androgens, we are in a position to look for extragenital effects. Of our series of patients, not one man requested treatment solely for any supposed enhancement of sexual capacity, but all state that they are benefited by the greater power of physical endurance. Vascular changes are characteristic, especially in the skin. The basal heart rate of the castrate is also increased when he receives androgens. McCullagh and Kenyon have shown that sufficient medication increases the basal metabolic rate and velocity of blood flow. These facts are mentioned, though they are not more significant than many of the other changes, such as the retention of salt, water and nitrogen described by Kenyon, Thorn and others. To some extent I must agree as to the obnoxious character of the temporary masculinization, but in these adult eunuchoids we have been able to obtain permanent masculinization with regard to only the lowering of the voice. That is the only change largely maintained for years after discontinuation of treatment. With the use of large doses, enlargement of the penis and of the genitalia occurs, but in our experience this tends to decrease after a while. We want to introduce a note of warning regarding the use of androgens in a woman who may be pregnant. This warning would apply also to the use of estrogens during possible pregnancy. Masculinization would not ensue, but there might be hypospadias, perhaps failure of testicular descent and a tendency toward development of female organs. There is indubitable evidence from animal experiments that pseudohermaphroditism can be and is produced by the influence of sex hormones at critical times during pregnancy.

Dr. KARL JOHN KARNAKY, Houston, Texas: We have used androgens in several hundreds of cases in the Menstrual Disorder Clinic at the Jefferson Davis Hospital, Houston. We have used androgens routinely as advocated but have almost discontinued their uses entirely. Androgen is used occasionally in the menopausal patient. It was my good fortune to discover that diethylstilbestrol would stop functional uterine bleeding in five to thirty minutes when given in doses of 25 to 100 mg. into the anterior lip of the cervix. It was also discovered that diethylstilbestrol would cause atrophy of follicular cysts of the ovaries. In my opinion it is almost always retentive cysts of the ovaries that cause functional uterine bleeding, and diethylstilbestrol will eliminate the cause of the bleeding by causing follicular cysts to atrophy. Our clinic has studied more than 500 ovaries after giving androgen (testosterone propionate) and diethylstilbestrol. After giving from 100 to 5,000 mg. of androgen we never could get complete atrophy of all the follicular cysts, while with diethylstilbestrol it required 100 mg. over a period of twenty days to eliminate completely all the

follicular cysts of the ovaries. Diethylstilbestrol has almost eliminated hysterectomies in cases of functional uterine bleeding. We have 700 cases of uterine bleeding in our series, in 500 of which we would previously have done a hysterectomy. We seldom do a hysterectomy just because of uterine bleeding. After more than 5,000 endometrial biopsies which were taken after all the way from 1 to 40,000 mg. of diethylstilbestrol had been given, estrogens, as far as we can observe, do not cause carcinoma. We have also shown that there is no such thing as a bleeding factor because we have produced uterine bleeding in children, and in women who have had radium or roentgen rays. Estrogenic hormones are apparently the bleeding factor.

DR. UDALL J. SALMON, New York: I regret that the impression has been created that androgen therapy in women inevitably results in the development of masculinization. This is an unfortunate misconception, since it creates an unjustified bias against a valuable therapeutic agent. We have treated more than 420 women with androgens for various gynecologic disorders and have encountered some degree of hypertrichosis or hoarseness in about 7 per cent of the cases. This includes those cases which were treated during the early experimental stage of this study, when we were interested in exploring the biologic properties of the androgens. With that end in view we had administered huge doses, in some instances more than 1,500 mg. during one month. Our studies have shown that there is a definite threshold for the induction of these masculinization phenomena, which is about 500 to 600 mg. of testosterone propionate a month. The therapeutic dose is very much below this, varying from 100 to a maximum of 300 mg. a month. There are, however, some individual variations in androgen susceptibility. Brunettes with a slight hypertrichosis appear to be the most susceptible. The average woman with no antecedent hirsuties can be safely given the therapeutic dose without fear of inducing hypertrichosis. We have found that frequently the smaller doses (100 to 200 mg. a month) will achieve satisfactory therapeutic results, particularly in cases of dysmenorrhea, premenstrual tension and mastalgia. With these smaller doses we have encountered no arrhenomimetic effects in over 200 cases. Furthermore, as regards avoiding these arrhenomimetic phenomena, there are certain morphologic signs which indicate androgen saturation. This is determined most simply by the vaginal smear, which can be prepared in a few minutes. The changes in the vaginal cells precede the appearance of the masculinization phenomena, so that the vaginal smears can serve as a simple method of guarding against overdosage. It is also worthy of note that the arrhenomimetic phenomena spontaneously regress after the discontinuation of the androgens. In regard to the danger of carcinogenesis resulting from estrogen therapy, Dr. Geist and I have conducted a study of this problem during the past six years on over 200 patients who had been treated with large doses of estrogens, and during the last two and one-half years on 180 patients who have been implanted with estrogen crystals and pellets. In these cases, periodic biopsies of the endometrium and vaginal mucosa failed to reveal any evidence of any atypical or neoplastic proliferation.

DR. SAMUEL H. GEIST, New York: The questions raised in the discussion are so numerous and so broad that it would be impossible in a short time to attempt even to touch on all of them. There is one thing that I wish to stress, which Dr. Pratt sensed immediately: this work as presented is experimental. After all, there must be some venturesome spirits among us if we are to establish facts therapeutic or physiologic; and we class ourselves as pioneers in this interesting field. It is only after a long series of experiments by many individuals over a period of many years that we shall be able to establish the fact that androgens have a definite place in the treatment of gynecologic disease. It is possible that they will not. Just as the limitations have been put on estrogens so aptly and so correctly by Dr. Hamblen, so shall we eventually be able to evaluate properly the use and therapeutic indication for androgens in gynecology.

DR. E. C. HAMBLÉN, Durham, N. C.: There is only one comment which I should like to add: this is in regard to the so-called carcinogenic role of estrogens. Reference to possible carcinogenic effects by me was only for the purpose of repeating an old clinical warning. It is certain that, in clinical

practice, natural estrogenic hormones have not been given, as yet, in such doses and over such periods of time to justify any serious anxiety in this regard. If some of the various estrogenic chemical substances of the diethylstilbestrol type, however, are made available in commerce, their unsupervised employment, i. e. in self medication, their high potency when taken orally and their cheapness may afford a closer approximation of the conditions which have characterized the production of carcinoma by estrogens in experimental animals. Under these circumstances a real danger may be recognized.

BRONCHIOGENIC CARCINOMA

INCIDENCE IN THE PACIFIC NORTHWEST, WITH A
COMMENTARY ON EIGHTY-FOUR CASES

FRANK R. MENNE, M.D.

AND

MELVIN W. ANDERSON, M.D.

PORTLAND, ORE.

Bronchiogenic carcinoma is so designated because of the widely accepted conviction that all primary pulmonary malignant neoplasms of epithelial origin arise from the bronchi or their accessory glands. Most introductory commentaries describe the investigator's interest as being aroused by his encountering an unusual number of cases of bronchiogenic carcinoma. Such experiences with this serious affliction, until recently regarded as extremely rare, have given impetus to numerous dissertations on the subject in many parts of the world.

In like manner, the abrupt appearance of primary cancer of the lung (in 1926) in our autopsy services aroused our interest, and in 1931 we¹ analyzed the basic pathologic, clinical and radiologic characteristics in 16 cases. Shortly thereafter a visit to the different institutes of pathology in Europe elicited, on inquiry, the interesting fact that the percentage of bronchiogenic carcinoma observed at autopsy was increasing in all these institutes.

The literature contains many contributions to the knowledge of the origin, nature and consequences of this form of cancer. Notable among these have been the monograph by Simons,² the symposium by Halpert³ and the contributions by Ochsner and DeBakey.⁴ The reader is referred to these for a complete review of the literature. However, there remains some question as to the relative or absolute increase of the incidence, the cause, the exact pathologic classifications and the concomitant symptoms. For this reason additional evidence is herewith presented.

INCIDENCE

Simons, after an extensive review, expressed the opinion that there was an increase both relative and absolute. This conclusion has been supported by many subsequent investigators. Rice⁵ stated that there had been a decided increase in the last five years. Vinson⁶ observed a well defined increase ("as frequent as pul-

monary abscess") during the period 1925 to 1935. Rosedale and McKay⁷ found bronchiogenic carcinoma to constitute 7.5 per cent of all carcinoma, being third in the list. Alwens and his associates⁸ found a decided rise during the last ten years. Mattick and Burke⁹ reported that at the Institute for the Study of Malignant Diseases, of 30,000 persons admitted, showing 18,000 malignant tumors, 73 (1 in every 250) had bronchiogenic carcinoma. This condition occurred with half the frequency of carcinoma of the stomach. A similar comparative observation was reported by Halpert.³ Brines and Kenning¹⁰ also stated that primary malignant tumor of the lung had developed from obscurity to importance, comprising 10 per cent of all cancer in Germany and being second to carcinoma of the stomach, as observed at autopsy in 3,000 cases. Cramer¹¹ quoted Peters as pointing out that the bronchiogenic type of neoplasm has advanced from fifth to second place and that in 1930 it constituted approximately 28.05 per cent of all carcinoma in men. Howes and Schenck¹² found 3 per cent of all carcinoma in the Brooklyn Cancer Institute to

Fig. 1.—Composite curve illustrating the incidence of bronchiogenic carcinoma in the Northwest from 1920 to 1940, as observed at autopsy in 33,945 cases.

be bronchiogenic. Lockwood's¹³ percentage was somewhat greater, being 6 to 8. Lockwood further noted that twenty years ago the condition was diagnosed in only 5 per cent of patients during life, while today it is recognized clinically in 50 per cent. It was his conclusion that carcinoma of the lung is on the increase in spite of the improved methods of diagnosis. A report¹⁴ of the Chicago Tumor Institute for a period of two years revealed a smaller incidence of bronchiogenic carcinoma (1.14 per cent of all malignant tumors). Lovelock,¹⁵ while undecided as to the relative or absolute increase, pointed out that European authors often have expressed the view that the increase is relative and not absolute.

Discordant opinions have been voiced by several authors. Stein and Joslin¹⁶ expressed the belief that

the increase is due to greater diagnostic accuracy but observed that there was a steady increase as compared with the incidence of carcinoma of the larynx and the lip from 1931 to 1936. Brunn¹⁷ reported 488 instances in 192,271 necropsies (0.24 per cent) from 1898 to 1916. Jaffé¹⁸ noted an incidence of 11.47 per cent of all carcinoma, as compared with one of 10.73 per cent observed in an earlier series of autopsies performed in Vienna (1915 to 1918) and concluded that the increase is more apparent than real. Boyd¹⁹ pointed out that carcinoma of the lung is third in frequency, being exceeded only by carcinoma of the stomach and carcinoma of the large bowel. He recorded 53 instances among 4,500 autopsies (1.2 per cent) from 1925 to 1936 and 64 instances among 2,408 autopsies (2.6 per cent) from 1927 to 1937. This author commented that the worldwide character of the increased incidence has been "phenomenal . . . during the last twenty-five years." However, he concluded that the increase is more apparent than real and that it is due to the recognition of pulmonary carcinoma, the increased facilities for diagnosis and the increased number of autopsies. He further asserted that there was a parallelism between the increase of carcinoma of the lung and the increase of other diseases as revealed by vital statistics. He credited to the use of the bronchoscope and roentgen rays the earlier and more frequent recognition of bronchiogenic carcinoma. In addition, Boyd attributed to the inaccuracy of the differential diagnosis of certain types of bronchiogenic carcinoma from such conditions as Hodgkin's disease and lymphosarcoma a false increase in the incidence of carcinoma of the lung. Middleton²⁰ regarded the increased span of life and the "clinical and pathologic diagnostic consciousness" as being in part responsible for the apparent gross increase.

Our own experience in the study of the incidence of bronchiogenic carcinoma has been at variance with the conclusion that the increase is more apparent than real. Accordingly, it was decided to determine the occurrence of bronchiogenic carcinoma in the Pacific Northwest. We therefore sent a questionnaire to the members of the Pacific Northwest Society of Pathologists, requesting the incidence observed at autopsy. An analysis of the returns disclosed that from 1920 to November 1940, 33,945 postmortem examinations were made, revealing a total of 517 instances (1.52 per cent) of primary bronchiogenic carcinoma. Some of these were recognized by biopsy and others by combinations of clinical observations, biopsy and final autopsy. For recording the instances, the 20 years was divided into four five-year periods. During the first period, 1920 to 1925, only 3 instances were recorded, 1 at the University of Oregon Medical School (department of pathology) and 2 at the Good Samaritan Hospital. In the second period, 1926 to 1930, 63 cases were noted; from 1931 to 1935, 201, and from 1936 to 1940, 407. The striking increase in the last period as compared with that in the first is undoubtedly due in part to better diagnostic facilities and the presence of pathologists in institutions which had previously had none except in the Vancouver General Hospital, the University of Oregon Medical School and the Good Samaritan Hospital, where both diagnostic facilities and pathologists were available during the entire twenty years. It is significant, however, that during the last two periods, namely 1931 to 1935 and

1936 to 1940, there was an astounding and sharp rise in the incidence. A composite curve (fig. 1) based on the number of carcinomas occurring in the respective five year periods reveals a striking continuous elevation. It has been argued that the greater knowledge of the disease, the increased facilities for diagnosis and the greater number of autopsies adequately explain the greater number of occurrences throughout the two later periods. To ascertain if this was true we compared the yearly percentage of bronchiogenic carcinoma with the number of autopsies in two of the institutions in which trained pathologists had been present during the twenty years and in which diagnostic facilities were standardized in accordance with the developments of the period. It will

In order to determine the accuracy or inaccuracy of the seemingly convincing data, a further analysis of the incidence was made (fig. 3), based on a segregation of the cases of bronchiogenic carcinoma (in the same two institutions) as observed at autopsy during a particular period, into groups of not less than 20.²¹ From 1928 to 1933 there were performed at the University of Oregon Medical School 3,129 autopsies, disclosing 23 cases of bronchiogenic carcinoma (0.73 per cent); from 1934 to 1937 there were 2,820 autopsies, disclosing 26 cases (0.92 per cent), while from 1936 to November 1940 there were 2,022 autopsies, disclosing 34 cases (1.68 per cent). Comparatively, in the Vancouver General Hospital from 1928 to 1933 there were 2,111

Fig. 2.—Relation of the incidence of bronchiogenic carcinoma to the number of autopsies performed from 1926 to 1940 inclusive.

be noted (fig. 2) that while there was a continuous, steady elevation in the number of autopsies performed throughout the years the percentage of bronchiogenic carcinoma did not parallel the increase in the number of autopsies for a given year and that not infrequently when there was a rise in the number of autopsies there was an actual decrease in the number of bronchiogenic carcinomas. It must be borne in mind that a rising total of autopsies also includes those performed on persons who have died from all causes. Epidemics of influenza or increased numbers of cases of pneumonia and other acute conditions may increase the number of deaths and the percentage of autopsies so that there may be an actual fall in the relative percentage of bronchiogenic carcinoma based on the total number of autopsies performed.

autopsies, disclosing 35 cases of bronchiogenic carcinoma (1.65 per cent), from 1934 to 1937, 2,206 autopsies and 40 cases (1.81 per cent), and in the final period (1938 to November 1940) 2,244 autopsies and 56 cases (2.49 per cent) (fig. 3). There is a striking parallelism in the incidence similar to that seen in figure 2.

The higher percentage at the Vancouver General Hospital in the periods stated may be attributed to less generalization in the performance of autopsies. That is to say, a greater percentage of autopsies may have been performed on all patients with bronchiogenic carcinoma, because of the unusual character of their disease, than

21. In determining the variations due to the laws of chance, as evidenced in a mathematical curve, a reasonably uniform number of not less than 20 must be selected. The greater the number in groupings of this kind, the more accurate is the percentage.

on patients with other conditions, whose death was not due to a malignant tumor. However, the number of cases during these periods at the Vancouver General Hospital was almost twice as great as that at the University of Oregon Medical School. By the same token, the percentage of error in estimating the incidence would be twice as accurate as that used in estimating the inci-

Fig. 3.—Relation of the incidence of bronchiogenic carcinoma to the number of autopsies performed in the University of Oregon Medical School and in the Vancouver General Hospital during three year periods.

dence at the University of Oregon Medical School. Since there is a striking parallelism, the accuracy of the incidence is enhanced. It would seem, therefore, from the preponderance of evidence submitted in reports in the literature as well as from a careful analysis of our own statistics and those available in the Pacific Northwest, that there is both a relative and an absolute increase of bronchiogenic carcinoma.

ETIOLOGY

Since it seems evident that there is an absolute increase, the reason for it becomes of paramount importance. (See Simons² and others for detailed consideration.) The disease may be in such an early stage and so indefinite in its clinical aspects (Middleton²⁰) as to escape detection until therapeutic procedures become extremely difficult. Even when it is recognized in the early stages, radical surgical removal has its dangers both as to mortality and as to altered physiology. All other methods of therapy are still of questionable value. It is accordingly of vital importance to consider the possible causes and to institute proper preventive measures. Unfortunately, study of our own series of cases as well as others yields nothing but speculative opinion as to the possible cause of bronchiogenic carcinoma. Much stress has been laid on the influence of prolonged and severe respiratory infections (e. g. influenza, pneumonia, tuberculosis) by Rice,⁵ Vinson,⁶ Brines and Kenning,¹⁰ Cramer,¹¹ Turner and Willis,²² Dressler and Weigl,²³ Kramer and Som,²⁴ and others. We also have been convinced that any continuous respiratory irritant or infection producing repeated denuding with reepithelization of the bronchial mucosa will either result or aid in the establishment of a malignant pattern.

Contamination of the air in areas of congested traffic and industry is receiving increased attention. Rosedale and McKay⁷ and Dressler and Weigl²³ incriminated chromate dust as provocative in chemical industrial workers. Continued emphasis is being placed on the role of coal dust, chemical agents, radioactive substances

and silicosis in mining and other industries (Charr,²³ Stein and Joslin,¹⁶ Turner and Willis,²² Lockwood,¹³ Lovelock,¹⁵ Lynch and Smith²⁶ and Dressler and Weigl²³).

More recently investigators have turned their attention to the possible influence of the increased use of smoking tobacco (especially the marked increase in the use of cigarettes). Myers²⁷ pointed to the enormous increase in the number of cigarettes consumed in this country. In 1880, 582,718,995 cigarettes were consumed, in comparison with 169,847,245,964 in 1937. Myers noted also that the toxic products of the combustion and distillation of tobacco are carbon monoxide, ammonia, formaldehyde, methylamine, methane, methyl alcohol, hydrogen sulfide, pyridine, furfural, arsenic and hydrocyanic acid. Of these the nicotine and tar contents are thought to be the most harmful. The former is an irritant of mucous membranes and the latter is regarded as carcinogenic. Myers²⁷ stated that "the smoking habits unquestionably increase the liability to cancer of the mouth, throat, esophagus, the larynx and the lungs." Cramer¹¹ noted that habitual smoking producing chronic inflammation of the mouth, pharynx, larynx and bronchial mucosa was present among the steel workers studied by him. In comparing the influence of tobacco smoking with that of the gases coming from automobile exhausts, Cramer¹¹ demonstrated that a 5 Gm. cigar yielded 200 mg. of tar (phenanthrene), while an eight hour drive 10 meters behind an automobile resulted in the collection of only 1.5 mg. of a similar tar. This author appeared to be convinced of

the influence of tobacco smoking in the causation of bronchiogenic carcinoma. Roffo²⁸ stated that "the tobacco tars are very strong cancer producing" agents and that they are in the "same form as the coal tars and certain substances whose properties are very like those of the hydrocarbons distilled out of coal in their fluorescence and their spectrometry." He produced

cancers by the application of tobacco tars to the ears of rabbits. He pointed out that "one can easily see large opportunity of cancerization in a regular smoker who consumes 1 kilogram of tobacco monthly, which means 70 cc. of tar." In this manner Roffo²⁸ reasoned that "the average smoker loads in one year 840 cc. and in ten years over 8 liters of tar on his buccopharyngo-

Fig 4—Encasement of the left primary and secondary bronchi by the new growth, hilar nodular bronchiogenic carcinoma

laryngopulmonary membranes, which certainly have not the biologic resistance of the skin of a rabbit." Turner and Willis²² observed bronchiogenic carcinoma in a gold miner who had influenza and smoked $\frac{1}{2}$ pound (226 Gm.) of black tobacco a week.

Certainly the striking predominance of bronchiogenic carcinoma in men as compared with the incidence among women suggests either that in the industries men come in contact with an irritating substance or that the increased consumption (smoking) of tobacco by men as compared with its use by women is of great significance. It would seem that more careful recording of the histories to how much particular persons smoke would be of great value in determining the causal relation of the use of tobacco to bronchiogenic carcinoma. The average inquiry simply elicits information that the patient is or is not a user of tobacco. It is too early as yet to observe in the statistics of the literature the possible influence that tobacco smoking may exert on the incidence of bronchiogenic carcinoma in women, who are now smoking cigarets, often more excessively than do men. A report by Rice,⁶ although it concerned a small number of patients (18 men and 12 women) seemed to indicate an increase among the women.

It seems obvious that the causative agent producing bronchiogenic carcinoma not only is air borne but is in a volatile state, since it involves the two lungs with almost equal frequency. Adequate information concerning correlative inflammatory phenomena in relation to the cause of bronchiogenic carcinoma is not at hand, since the average postmortem examination fails to comb completely the lung structure for initial lesions which might more accurately betray the influence of such phenomena. In the 4 instances of early bronchiogenic carcinoma to be reported by Hunter and his associates,²⁹ there were no clinical or gross pathologic evidences of such lesions. They were accidentally uncovered in the routine selection of lung tissue for histologic study. Here then lies a field that needs more intensive tilling.

At the time fully developed carcinoma of the lung is recognized there is considerable difficulty in defining cause and effect.

PATHOLOGY

In a previous communication we¹ discussed the extrinsic manifestations of the disease in relation to the existence of bronchiogenic carcinoma. At the time we pointed out that in 75 per cent of the instances there was bilateral chronic fibrous pleuritis indicating a previous inflammatory process of some moment. In addition there were acute empyema and other changes due to metastatic extensions in the mediastinum. In the majority of the instances the disease process had progressed so as to produce retraction of the mediastinal structures in the direction of the involved lung.

We were able to determine two more or less definite outstanding macroscopic types. One, in which the major lesions, at least in the less advanced stages, seemed to be that of maximum hilar accumulation, we designated the hilar nodular type; another, in which there was a diffuse involvement with a minimum of hilar concentration, was termed the diffuse necrotic type (figs. 4 and 5). Among 56 cases of bronchiogenic carcinoma in which autopsy was performed the carcinoma was of the hilar nodular type in 35 (62.5 per cent) and of the diffuse necrotic type in 21 (37.5 per cent). Regional pulmonary or lymphatic metastases occurred in all instances. Distant metastases were observed in 45. Whether this gross classification is of value may be open to question. Simons² quoted Aschoff as applying a macroscopic classification as follows: "(1) small nodular masses arising from bronchi of the first to the third order; (2) the infiltrating type in which a large portion of the lung or an entire lobe is involved." Rabin and Neuhoof,³⁰ in a morphologic study of 100 cases (in which autopsy was done), divided bronchiogenic carcinoma into two main types, "circumscribed and noncircumscribed." The foregoing concepts of the pathologic classification of bronchiogenic carcinoma are similar to the one advanced by us in a previous communication.

Our studies led us to conclude that the majority of cancers of the lung arise in the primary and secondary

Fig 5—Diffuse character of the involvement of the lung, diffuse necrotic bronchiogenic carcinoma.

divisions of the bronchi. At autopsy confusion of growth and its consequences make localization difficult. Carcinoma of the so-called diffuse necrotic type in general arises in the more distal bronchi; however, variations in type are not entirely due to location but are in part patterns of a varied pathogenesis. Vinson⁹

²⁹ Hunter, W. C.: Unpublished data.

³⁰ Rabin, C. B., and Neuhoof, H. A.: *J Thoracic Surg* 4:147 (Dec) 1934.

observed primary carcinoma in the trachea in 4 cases and in the bronchi in 87. Kramer and Som²⁴ concluded that 80 to 90 per cent originated in the bronchi, with 20 per cent of "parenchymal" origin. There is unanimity of opinion as to the more or less equal involvement of the lungs with a slightly increased incidence in the right (ratios given are, e. g., 6:4, 20:16 and 38:33). Of the 56 instances observed by us in detail, carcinoma was in the right lung in 28 and in the left in 27. Kramer and Som²⁴ in 100 postmortem examinations found the distribution of bronchiogenic carcinoma to be as follows: in the right lung—main bronchus 18, upper lobe 31, middle lobe 1 and lower lobe 12; in the left lung—main bronchus 8, upper lobe 17 and lower lobe 13. Carcinoma is observed in almost twice as many upper lobes as lower lobes. There is as yet no concrete evidence of bronchiogenic carcinoma's arising from atrial lining cells.

MICROSCOPIC STUDY

Many conflicting views are recorded as to the value and importance of histologic studies from both the academic and the practical point of view. Karsner and Saphir³¹ expressed the opinion that the histologic classification of bronchiogenic carcinoma is the most satisfactory. The observations of Fried³² with respect to the significance of the "reserve" cell type have permeated and influenced the considerations of the histology of bronchiogenic carcinoma. Practically all discussions confirm the existence of definite squamous cell types. The confusion of classification arises in proportion to the degree of anaplasia. Study of the cell structure of the tumors of 56 patients on whom autopsy was done revealed that 31 tumors were distinctly of the squamous cell type, with 9 disclosing keratinization, 15 showing no keratinization and 7 being distinctly anaplastic. Thirteen were found to be of the so-called adenocarcinomatous type, with only 2 showing mucus production. Eight were distinctly of the reserve cell type, 1 of the round cell type and 3 of the spindle or oat-shaped cell type. Again we wish to emphasize, as we did in our previous communication, that epithelial metaplasia with a subsequent malignant formation in the bronchi may result in all of the variable histologic types mentioned. We are of the opinion that with the so-called adenocarcinomatous type, except with growths arising from the mucous glands, the formation of acini is in part dependent on the structure of the lung and is more apparent than real. From the foregoing analysis it is obvious that the more or less confusing types of bronchiogenic carcinoma are decidedly in the minority. We refer in particular to the basal or reserve cell, round cell and spindle cell types. These constitute about 20 per cent of the total. There is, however, no particular confusion in recognizing the distinctly reserve cell type, so that there actually remains less than 1 per cent of primary carcinoma of the lung which may be confused with such lesions as lymphosarcoma. Vinson,⁶ using the Broders method of grading, pointed to its advantage in the application of various kinds of therapeutic irradiation. He concluded that the so-called adenocarcinoma is the most radiosensitive.

PATHOGENESIS

The progressive and subsequent pathologic changes in bronchiogenic carcinoma are obviously primarily dependent on the status quo of lung structure, the

bacterial flora and the site of the initial growth. When neoplasia originates in the primary or secondary bronchi, the direction of growth is, as we¹ have pointed out before, usually in the direction of the lumen. With the type designated by us as hilar nodular, analysis disclosed the sequence to be as follows: (1) hypertrophy, hyperplasia and metaplasia of the epithelium of the bronchus (carcinoma in situ); (2) partial or complete occlusion of the bronchus; (3) extension through the bronchial wall, with excitation of wandering cell infiltration and fibrosis; (4) further extension through the lymphatics; (5) involvement of the hilar lymph nodes, and (6) limited and slow massive extension into the lungs. With this type thromboses, coagulation necroses and secondary infectious processes are late in developing. The so-called diffuse necrotic type appears to us to be a manifestation of a more distant initiation in which the more delicate structure of the bronchus or bronchiole permits easier access to the surrounding lymphatics, with greater obstruction to the circulation. Primary carcinoma of this type appears to progress by (1) hypertrophy and hyperplasia of the epithelium (reserve cell type); (2) early extension into peribronchial lymphatics, with intrapulmonary lymphatic stasis; (3) engorgement and thrombosis of blood vessels; (4) secondary lobular pneumonic infection; (5) diffuse carcinosis; (6) coagulation necrosis with miliary abscess formation; (7) bronchiectasis limited to terminal bronchi, and (8) regional hilar node involvement, occurring in considerably less degree and later in the course of the disease. The carcinosis is characterized by spread through a definite lymphatic distribution in the lung as well as by continuity into tissue spaces. Pleurisy with effusion, because of extension to the pleura, is more frequent with this type. Furthermore, because of the earlier and more diffuse involvement of lymphatics and blood vessels, distant metastases (e. g. to the brain) are more common.

CLINICAL ASPECTS

No attempt will be made in this dissertation to analyze critically the various clinical concepts advanced in the literature by numerous writers. There is, however, universal agreement that the symptoms of bronchiogenic carcinoma are widespread and variable. Most writers on the subject agree that one must recognize two sets of symptoms and signs, those referable to the lungs and those arising from metastases in organs and tissues outside the chest. In our previous communication we attempted to correlate the symptoms, signs and radiologic data characteristic of bronchiogenic carcinoma in general and specifically of two more or less distinctive types (hilar nodular and diffuse necrotic).

In the present series of 84 cases, the average age was 55½ years, with a range of 38 to 77 years. In 78 cases the disease occurred in men and in 6 in women (13 to 1). These data are in agreement with those of the majority of reports. In a number of our cases adequate clinical data were not available, but in 44 of the 56 cases in which autopsy was done they were sufficiently complete to permit comparative evaluation of the signs and symptoms. In 29 of the 44 the carcinoma was of the hilar nodular type, and in 15 it was of the diffuse necrotic type (see accompanying table). An analysis of the salient symptoms and signs disclosed that cough with expectoration was the most frequent symptom, occurring in two thirds of the cases of both types of carcinoma. This was associated with hemoptysis in approximately half of the patients with hilar nodular

31. Karsner, H. T., and Saphir. *Otto*. Am. J. Path. 6: 553 (Sept) 1930.

32. Fried, B. M.: *Primary Carcinoma of the Lung*, Baltimore, Williams & Wilkins Company, 1932.

carcinoma (group 1) but in only 20 per cent of the patients with diffuse necrotic carcinoma (group 2). Dyspnea was the second most common symptom. It was especially severe in group 1 (occurring in 60 per cent) and less pronounced in group 2 (occurring in 40 per cent). Cyanosis was present in 13 per cent of the patients and was frequently stated to be a terminal event. The time and location of the pain were significant in that 20 per cent of the patients of group 1 complained of mediastinal pain characterized as dull, substernal and deep seated. This pain was not present in group 2, but the majority of patients in this group evidenced pleural pain, indicative of metastatic or inflammatory involvement of the pleura. The third type of pain in the chest, which is frequently credited to involvement of the intercostal nerves or roots, was present in only 1 patient of group 1.

In 8 instances the type of pain in the chest was unspecified, and in an equal number pain occurred in locations other than the chest. The pain in all 16 was due to metastatic involvement of organs and tissues evidencing distress.

A significant condition definitely related to the pathogenesis was atelectasis in 38 per cent of the patients with the hilar nodular type (group 1) and in 20 per cent of those with the diffuse necrotic type (group 2). Empyema, pulmonary abscess and gangrene, which are complications due to the extension of the growth and are evidences of secondary infection, tended to be more frequent in the patients of group 2. Hemothorax, in our series, occurred only in patients of group 2 (20 per cent). Hoarseness, stated to be a frequent complication of mediastinal extension, was present in 10 per cent of group 1 and in only 1 patient of group 2. Weakness and loss of weight were common complaints in both groups.

In summary, it may be pointed out that approximately half the patients with hilar nodular carcinoma presented symptoms referable primarily to the lungs, while an equal number had symptoms attributable to metastasis. On the other hand, of the patients with diffuse necrotic carcinoma twice as many had symptoms traceable to metastasis as had symptoms referable to the lungs. It is apparent that symptoms originating in the lungs, such as cough, expectoration and dyspnea, occur more frequently in the earlier stages of the disease and are more common in patients with hilar nodular carcinoma. Conversely, the symptoms and signs resulting from pleurisy, pulmonary abscess, empyema, hemorrhage, dyspnea, cough, hoarseness, aphonia and neurotic involvement are more frequent with diffuse necrotic carcinoma. Apparently the last six symptoms are due to the earlier tendency to metastasize as well as to the earlier obstruction of smaller pulmonary units and their surrounding lymphatics and blood vessels. While there may be some criticism as to the feasibility of the clinical and pathologic division of bronchiogenic carcinoma into the types described, it seems to us that the variability of the initial site of bronchiogenic carcinoma may be expected to and does result in fundamentally different clinical and pathologic pulmonary carcinomatous lesions.

SUMMARY

1. Bronchiogenic carcinoma was observed 517 times during a series of 33,945 autopsies performed in the Pacific Northwest.

2. Statistical analysis based on the number of autopsies, time periods and chance variations indi-

cates an absolute increase in the incidence of primary pulmonary carcinoma in recent years.

3. Emphasis is laid on the etiologic significance of inflammatory processes augmented by volatile irritants, such as tobacco smoke and gaseous products of the industries.

4. Eighty-four instances of bronchiogenic carcinoma were observed in the department of pathology; 78 of the patients were men and 16 women; autopsy was performed in 56 cases.

5. Bronchiogenic carcinomas are classified macroscopically into two types, hilar nodular and diffuse necrotic.

6. Histologic examination of the neoplasm in the 56 cases in which autopsy was done revealed that in 31 it was squamous cell carcinoma, in 13 so-called adenocarcinoma and in 12 reserve cell carcinoma.

ABSTRACT OF DISCUSSION

DR. HOWARD T. KARSNER, Cleveland: Although not always evident, there is value in analysis of the geographic distribution of disease. Climatic, occupational and perhaps dietary and other factors may be different in some respects in the Pacific Northwest from those which prevail elsewhere. It is therefore of interest to learn that bronchiogenic carcinoma is as common in that region as it is in other parts of the country. The authors review again the discussion concerning an increased incidence of this disease. There can be no doubt of a relative increase, but there may well be some question as to absolute increase. The population of the autopsy room is different from the living population, because it is a population determined by numerous factors of opportunity and interest. In ten years at the Cleveland City Hospital, 1927 to 1937 inclusive, bronchiogenic carcinoma constituted 9.4 per cent of all cases of malignant tumor examined at autopsy. No one would claim that about 1 of 10 living patients with malignant tumors has bronchiogenic carcinoma. If autopsy statistics were a guide in this connection it could be said that carcinoma of the lung arising in an obsolete primary tuberculous focus is on the increase because we have seen 3 such instances in the last year as compared with none in the preceding ten years. It is difficult to employ statistical analyses in determining absolute increase because there is no certain way to provide mathematical corrections that would fully account for improved diagnosis, special attention to the lesion, accurate interpretations of roentgenograms and precision of bronchoscopic examinations and biopsy. Nor are the errors inherent in the improved methods fully evaluated. For example, we have seen within a period of six months pneumonectomy in 2 cases not suitable for biopsy through the bronchoscope but characteristic in every way of bronchiogenic carcinoma. One was metastatic from a thyroid carcinoma treated surgically twenty years before and the other metastatic from an unnoticed malignant granulosa cell tumor of the ovary. No formula has yet been devised that meets all the factors of error, largely because these factors are not yet calculable. An absolute increase cannot be denied, nor is it fully established. The influence of various factors supposed to be responsible for an absolute increase is still in doubt. There is certainly no proved connection with epidemics of influenza, nor is there any frequency of association with pulmonary tuberculosis. Silicosis may be of importance but accounts for relatively few cases. Whatever accounts for the Joachimsthal cases does not prevail widely. If tobacco smoking were of significance, there should be an increasing incidence in women.

DR. BÉLA HALPERT, New Orleans: The contribution of Dr. Menne and Dr. Anderson presents evidence that there is a relative as well as an absolute increase in carcinoma of the lung. Their data from the Pacific Northwest on necropsy material are almost identical with those reported by Rosahn from the East and with our own data from the South. Carcinoma of the lung, in fact, is becoming the second if not the first most common malignant neoplasm in the male. Chronic irritations from infections, inhalation of gases, foreign bodies and

particularly smoking of tobacco with its nicotine and tar content may play a part, but perhaps more important is the fact that more people are reaching the cancer age. Whether the gross morphologic classification according to location and extent of the growth as suggested by Dr. Menne and the one by Dr. Karsner have any practical value remains to be seen. At present there are no gross criteria by which the cellular structure can be ascertained without microscopic examination. In looking for effective therapy the cellular structure is a decisive factor. It seems certain that successful radiotherapy of carcinoma of the lung is as yet impracticable. So, for the present, the only effective treatment is early recognition and, as suggested by Graham, Rienhoff, Overholt, Ochsner and DeBailey, Churchill and others, surgical removal of the involved lung—pneumonectomy.

DR. L. WALLACE FRANK, Louisville, Ky.: In my intern days, over twenty-five years ago, cancer of the lung was rare. Today it is exceedingly common. About four years ago I came to the conclusion that the probable cause of the increase of pulmonary cancer was related to the rapid increase in the number of automobiles and the increased use of tarred roads. I intended to work out a series of experiments to prove whether or not this was so but in studying the literature found that Campbell of England had already done the work. He studied mice, in which the known incidence of pulmonary carcinoma was 14 per cent. He took one group as controls and over the others blew twice daily the dust and scrapings from the roadways, most of which were made of some tar preparation. The incidence of pulmonary carcinoma in the second group was 76 per cent, compared with 14 per cent in the controls. I am of the opinion that Campbell's studies throw a great deal of light on the cause of the increase of pulmonary cancer.

DR. ISRAEL DAVIDSOHN, Chicago: When one evaluates all the factors which might have some significance in connection with the question of the absolute or relative increase of carcinoma of the bronchi, it seems worth while to point out the fact that until about 1926 the type of bronchiogenic carcinoma now referred to as reserved cell carcinoma was frequently mistaken for a primary sarcomatous growth of the lymph nodes in the mediastinum. The recognition of the true histogenesis of this tumor must of necessity influence the statistics of bronchiogenic carcinoma. I should like to ask the authors whether they have separated in their series the apical carcinoma originating in the peripheral bronchi, which, owing to its invasion of the bones in the region of the upper thoracic aperture and of the nerves, produces a very characteristic clinical picture (the so-called superior pulmonary sulcus tumor of Pancoast).

DR. FRANK R. MENNE, Portland, Ore.: As far as Pancoast's tumor is concerned, we did not encounter it. We have some papillary carcinomas occurring in association with apical scars that will be reported subsequently. I appreciate that several classifications of carcinoma of the lung have been advanced. Of course, when one deals with statistics one gets into trouble. I want to emphasize, however, again the fact that bronchiogenic carcinoma seems to me to be present out of all proportion to our increased knowledge, either clinically or pathologically, of this incidence, irrespective of the locality. I want also again to emphasize the fact that those carcinomas of the lung that are confused with primary tumors of the lymph in the lymph nodes or the lymphocytes or Hodgkin's disease are a small percentage of the bronchiogenic carcinomas that have been present in our experience.

Lazy Medicine.—That sort of medicine is lazy medicine. It is easier to get the answer out of a machine or out of laboratory reports than to sit down and think for yourself. Or at least the users of the machine think it is. In any event, it satisfactorily puts off until tomorrow, and perhaps forever, the examination you don't want to make today. The machine is made a substitute for thought. Unfortunately it is not invariably the correct answer which comes out; sometimes the machine speaks with the guile of the Delphic oracle, though the hearer does not realize it. And machine medicine may be not only lazy medicine, it may be dishonest medicine.—Atkinson, Miles: *Behind the Mask of Medicine*, New York, Charles Scribner's Sons, 1941.

NORMAL AND ABNORMAL BACTERIAL FLORA OF THE NOSE

LEON ORRIS JACOBSON, M.D.

AND

GEORGE F. DICK, M.D.

CHICAGO

The frequency with which an abnormal bacterial flora was found in cases of frank nasal infection and in the nasal passages of persons without objective changes in the nasal mucosa or subjective symptoms of sinus infection led us to undertake a systematic and comprehensive study of the bacteriology of the nose.

METHODS

The nasal secretion of 500 consecutive patients admitted to our general medical service was cultured. The age of the patients varied from 4 weeks to 78 years. Cultures were made by inserting a sterile swab far back into the nasal cavity and streaking a blood (sheep blood) agar plate directly. Material from each side of the nose was cultured separately. In some cases cultures were made in the same manner with Löffler's medium. Cultures were made of sterilely obtained antral washings by inoculating nutrient broth, dextrose broth and blood agar plates. Cultures thus obtained were incubated at 37.5 C. for twelve to twenty-four hours, and the organisms were then identified by the appearance of the colonies, appropriate staining procedures and bile solubility tests. In many instances, cultures were made repeatedly during the initial hospitalization, return visits of outpatients or readmission.

RESULTS

The organisms found in the nasal passages varied considerably except for the constant presence of *Staphylococcus albus* and diphtheroid bacilli (table 1).

In every instance except 2 in which organisms other than staphylococci, diphtheroid bacilli and *Micrococcus catarrhalis* were isolated on culture from the nasal passages, abnormal changes or conditions existed in the nasal cavity and/or the paranasal sinuses. The 2 exceptions were the only instances in which green-forming streptococci were isolated from the nasal passages and could not be found on repetition of the culture. No abnormalities were demonstrable either clinically in the nasal cavity or by roentgenogram in the paranasal sinuses in these 2 cases. On the other hand, staphylococci and diphtheroid bacilli were found on culture in every case, whether or not there were objective changes in the nasal passages or the paranasal sinuses. Cultures of nasal secretion taken from patients with the "common cold" or an increased nasal discharge from any cause always showed an increase in the number of colonies of staphylococci and diphtheroid bacilli, regardless of what other organisms, if any, might be present. Children with the "common cold" frequently had pneumococci in the culture.

The organisms cultured from material from the nasal passages (other than staphylococci, diphtheroid bacilli and *M. catarrhalis*) were associated with many varied abnormalities of the upper respiratory tract. Sinusitis of the acute purulent, chronic purulent or chronic hyperplastic (nonpurulent) type was the condition most frequently encountered. The cultures of nasal secretion (tables 2, 3 and 4) most frequently showed green-forming streptococci, pneumococci or hemolytic strepto-

cocci. Pneumococci and hemolytic streptococci were found most often in cases of acute sinusitis and green-forming streptococci in cases of chronic sinusitis. In approximately 20 cases green-forming streptococci were recovered from the nasal passages although clinical evidence of sinusitis and frank changes in the nasal mucosa were absent. However, in these cases nonsuppurative (hyperplastic) maxillary sinusitis was shown by roentgen examination. In a few instances green-forming streptococci were recovered from only one nasal passage, with roentgen evidence of sinusitis on the same side.

Hemolytic streptococci were cultured from material from the nasal passages in 15 of the 19 cases of scarlet fever, and occasionally green-forming streptococci were found. Pneumococci were cultured in 2 cases of lobar pneumonia, in one of which there was purulent pansinusitis. Likewise, diphtheria bacilli were cultured from the nasal secretion of 1 patient with clinically diagnosed pharyngeal diphtheria and from that of a diphtheria carrier who had chronic suppurative sinusitis. The latter had, in addition, both green-forming streptococci and hemolytic streptococci in the culture. *Bacillus mucosus* was found on culture in 2 cases of chronic atrophic rhinitis. In 1 of these hemolytic streptococci and pneumococci were also present, and in the other, hemolytic streptococci, diphtheria bacilli and green-forming streptococci. Both patients had a chronic form of maxillary sinusitis. Pfeiffer's bacillus was isolated from the nose in 1 case of clinically diagnosed influenza. Other conditions or lesions in association with which such organisms were found were nasal obstruction due to a markedly deviated septum, with reddened, wet mucous membranes; septal abrasions, and ulcers.

TABLE 1.—Frequency of Various Organisms in Cultures of Nasal Secretion of Five Hundred Patients

Organism	Occurrence	Percentage
<i>Staphylococcus albus</i>	500	100
Diphtheroid bacillus.....	500	100
Green-forming streptococcus.....	104	20.8
<i>Staphylococcus aureus</i>	7.2
Hemolytic streptococcus.....	36	7.2
.....	35	7.0
.....	6	1.2
.....	3	0.6
.....	2	0.4

Percentage showing sinusitis.....	60.44

Green-forming streptococci or pneumococci were isolated from the antral washings of a number of patients who showed clinical and roentgen evidence of sinusitis.

COMMENT AND REVIEW OF THE LITERATURE

Bacteriology of the Nose.—The flora of the nasal passages has been studied by many observers. In 1898 Park and Wright¹ reported that the normal nose is not usually sterile but that organisms such as pneumo-

cocci and streptococci are rarely found. Neumann² in 1902 studied the nasal flora of more than 200 persons, 111 of whom were supposedly normal, with the results shown in table 5.

None of the patients in Neumann's study had roentgenograms of the paranasal sinuses made.

TABLE 3.—Normal Nasal Flora and Roentgen Evidence of Sinus Disease

Number of patients with normal nasal flora.....	339
Number of roentgenograms of paranasal sinuses.....	181
Number of roentgenograms showing evidence of sinusitis.....	20
Percentage showing sinusitis.....	11

TABLE 4.—Frequency of Organisms in Cases of Roentgenologically Proved Sinusitis in Association with an Abnormal Nasal Flora

Number of cases of an abnormal flora plus roentgen evidence of sinusitis.....	58
Number of cases in which there were green-forming streptococci.....	45, or 77.56%
Number in which pneumococci were found on culture of nasal secretion.....	9, or 15.51%
Number in which hemolytic streptococci were found on culture of nasal secretion.....	4, or 6.8%

Bloomfield³ found that *Staph. albus* was present in every culture of nasal secretion and regarded its presence as a normal condition. Less frequently he found diphtheroid bacilli and *Staphylococcus aureus* and considered gram-negative cocci, *B. lactis aerogenes* and hemolytic streptococci to be transient forms. This view was held essentially by Noble and Fisher⁴ and by Noble and Brainard.⁵ They concluded that organisms such as hemolytic streptococci, green-forming streptococci and pneumococci, of known potential pathogenicity, are clinically significant only in the presence of a definite lesion in the nasal cavity but in the absence of a clinical lesion may be considered transients. According to our experience, whenever these organisms can be cultured from material from the nasal passages, changes in the nasal mucosa or secretion or in the paranasal sinuses are present. Webster and Hughes,⁶ in a study of the epidemiology of pneumococcal infection, expressed the belief that persons from whom pneumococci could be constantly recovered were infected persons in the sense that the organisms were growing in the rhinopharyngeal tissues. These chronic carriers, according to their report, were not given a roentgen examination to determine whether paranasal sinusitis might have accounted for the repeated positive cultures.

Neufeld and Etinger,⁷ in a study on children (aged 1 to 20 months) with acute coryza, found pneumococci in 65 per cent of cultures of nasal secretion. Our observation on children was similar except that pneumococci were found more frequently than green-forming streptococci when there was evidence of an infection of the upper respiratory tract. Dochez⁸ studied 13 adults between October and June, making cultures of material from the nose and throat weekly when the person was in normal health and daily when a cold occurred. Their observations on the normal nasal flora agree essentially with those of the authors previously cited as well as with our own with respect to the frequency of staphylococci and diphtheroid bacilli. They concluded that gram-negative cocci and nonhemolytic streptococci are occasional transients in the nose but that in the presence of colds hemolytic streptococci and Pfeiffer's bacilli are frequently found. In our series green-forming streptococci and pneumococci were found during colds as frequently as hemolytic streptococci and more frequently than Pfeiffer's bacillus. Wirth and Braun⁹ studied the bacteriology of the nose and throat during acute infections of the upper respiratory tract and concluded that the nasal passages assume a sympathetic role to one another, especially when hemolytic streptococci, pneumococci and influenza bacilli are the causative organisms. This conclusion came as a result of finding the organisms on culture of material from both sites so frequently. Wirth's¹⁰ observations agree essentially with this observation, if one assumes that examination of the nasal bacteria was

the easiest method of determining the causative agent of infections of the ear and the upper respiratory tract.

In isolated instances other organisms have been found in cultures of nasal secretion. Meyer and Steenert¹¹ isolated the tubercle bacillus from the purulent nasal discharge at autopsy. Kistner¹² isolated the same organism from the nasal discharge of a person with a primary nasal tuberculoma. Schroeder¹³ found diphtheria bacilli in 39 of 126 cases of chronic atrophic rhinitis and, in a few of these, *B. mucosus*. The diphtheria bacilli were identified by culturing the nasal secretion on Löffler's medium and appropriate Gram staining of the growth. Reference has already been made to our finding diphtheria bacilli in 1 of 2 cases of atrophic rhinitis. Jelin¹⁴ found *B. mucosus* frequently in cases

of atrophic rhinitis but concluded that this organism was not necessarily associated with the rhinitis. On the contrary, Elbert and Guerkess¹⁵ concluded that *B. mucosus* was significant and its presence a relatively constant finding in association with atrophic rhinitis and rhinoscleroma. Mackey¹⁶ reported a study of 85 children suffering from chronic nasal catarrh in whose nasal secretion he frequently found Pfeiffer's bacillus, *Bacillus pertussis* and *B. mucosus*. Miller¹⁷ reported finding gonococci in the nasal secretion of a child with nasal infection and gonorrheal vaginitis. The organisms were identified by finding gram negative intracellular diplococci in the nasal secretion and differentiating them from the meningococcus by appropriate culture methods. Bordet¹⁸ and Moncrieff and Lightwood¹⁹ found *B. pertussis* in the nasal secretion of children with clinically diagnosed whooping cough. Hollender²⁰ and Shulman²¹ isolated Vincent's fusiform bacilli and spirochetes in 2 cases of nasal infection. Fishbein and Staff,²² studying a series of nasal infections, concluded that although staphylococci predominated in the largest number of cultures, the patients with streptococcal infections were the ones showing the most clinical symptoms, such as nasal discharge, obstruction to breathing, headache and lassitude. Tilley²³ studied the bacteriology of purulent nasal discharge and found that the flora was generally mixed but that staphylococci, streptococci and pneumococci were in evidence.

Bacteriology of the Sinuses.—Several observers, Toerne,²⁴ Linton,²⁵ Lewis and Turner²⁶ and Frankel,²⁷ studying clinically normal sinuses at autopsy, agreed that the sinuses are sterile in health. Frankel found that the pneumococcus was the predominant organism in sinuses which showed gross pathologic change. Oaks, Merrill and Oaks²⁸ studied the bacteriology of antral washings and found one or both of the maxillary sinuses sterile in 234 of 475 patients who came to treatment because of what they presumed to be sinus infection. No mention is made of the different types of organisms found, nor were roentgen studies made, but Oaks and his associates concluded that there are bacteria characteristic of sinusitis. Jenssen²⁹ concluded that normal sinuses are sterile but that there are

no bacteria characteristic of sinusitis. Lederer and Livingston³⁰ and Collet³¹ found the tubercle bacillus in 2 cases of maxillary sinusitis. Jay³² described a case of maxillary sinus infection in which fusiform bacilli and spirilla were isolated. Ersner³³ made cultures in cases of maxillary sinusitis requiring operation and found that hemolytic and green-forming streptococci predominated but were most often found in association with nonsuppurative conditions. Lewis and Turner³⁴ made cultures of material from the antrum in 100 cases of suppurative maxillary sinusitis and isolated Pfeiffer's bacillus in 4, but streptococci, pneumococci and staphylococci predominated. Crowe and Thacher-Neville³⁵ studied 100 cases of paranasal sinus infection. Cultures of antral material taken at operation revealed streptococci (usually green-forming but occasionally hemolytic) to be the predominant organisms but Pfeiffer's bacillus and pneumococci were found occasionally. Babcock³⁶ concluded from culturing antral material that the pneumococcus is predominantly associated with acute sinusitis and green-forming streptococci with chronic sinusitis. Wirth³⁷ cultured material obtained from the antrums of 50 patients with purulent sinusitis. The predominating organisms encountered were Pfeiffer bacilli, hemolytic streptococci and pneumococci, staphylococci being seen but once. Kistner³⁸ studied nonsuppurative or "hyperplastic sinusitis," which he assumed to be a latent stage of sinus infection. Tissues removed from the antrums at operation were ground and washed in sterile sand and cultured. Material from more than 400 sinuses was thus cultured. A mixture of bacteria was usually present, but in 94.5 per cent streptococci were found, of which 35 per cent were hemolytic green-producing streptococci of type A, 14 per cent *Streptococcus viridans* and 18 per cent nonhemolytic streptococci of the gamma type. In addition to and in combination with the streptococci there were found, in order of frequency, staphylococci, *M. catarrhalis*, pneumococci, Friedlander's bacillus, the influenza bacillus, the colon bacillus, diphtheroid bacilli and streptothrices. Contrary to the observations cited, Ashley and Frich³⁹ found *Staph. aureus* more frequently than any other organism in a bacteriologic study of maxillary sinus infections in children.

SUMMARY AND CONCLUSIONS

Cultures of nasal secretion were made as a matter of routine for 500 patients admitted to a general medical service, none of whom had been admitted because of

a primary complaint referable to the nose or the paranasal sinuses.

We find in agreement with most observers that the normal nasal flora consists chiefly of *Staph. albus* and diphtheroid bacilli, with *Staph. aureus* and *M. catarrhalis* less frequently.

Green-forming streptococci and pneumococci are occasional transients in the nasal cavity.

The presence of streptococci, pneumococci, *B. mucosus*, Pfeiffer bacilli and diphtheria bacilli indicates disease of the nasal mucosa or sinus disease or both.

The frequency with which green-forming streptococci, hemolytic streptococci and pneumococci were isolated by culture of nasal secretion in cases of sinusitis, acute or chronic, shows the diagnostic value of this simple, inexpensive procedure.

KAOLIN GRANULOMA OF THE STOMACH

ALLAN L. COHN, M.D.

ALFRED S. WHITE, M.D.

AND

HELEN B. WEYRAUCH, M.D.

SAN FRANCISCO

The harmful effects on the human body of silica and certain silicates have been known for many years. While references to the lesions in the lung are numerous and the changes caused by silicates in the muscle, peritoneum and serosa have been described, there have to our knowledge never been recorded the pathologic results of the silica group in the human stomach.

We present herewith a case of granuloma of the stomach which followed ingestion of medication containing colloidal kaolin (hydrated aluminum silicate, $\text{Al}_2\text{Si}_2\text{O}_8 + 5\text{H}_2\text{O}$) together with the results of preliminary experiments in rabbit stomachs using the same medicinal preparation.

PATHOLOGIC CONDITIONS CAUSED BY SILICA AND SILICATES

Silica and certain silicates cause characteristic reactions in tissue. This is a proliferative type of reaction in which there are nodules with mononuclear or giant cells enveloped by a fibrous tissue beyond which are scattered lymphocytes. There is great similarity of the reaction to that produced by the tubercle bacillus. Numerous authors have described this in detail.¹

Gardner,² demonstrating the similarity of lesions produced by silica and the tubercle bacillus, showed that

From the Mount Zion Hospital.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

Dr. Franklin I. Harris, chief of surgery, gave permission to study this case. The pathologic investigations were made under the direction of Dr. G. Y. Rusk, chief pathologist to the Mount Zion Hospital. Mr. John Finn, consulting chemist for the State of California Compensation Insurance Fund and the Newmont Mining Company, collaborated in the mineralogical studies.

the giant cells which develop in the tissues reacting to silica are not of the ordinary foreign body giant cell type. They resemble the Langhans cell of tuberculosis.

Silica (Si_2O), probably most active in colloidal form,³ produces the typical lesion of silicosis, but certain of the silicates are also active dusts and produce a similar type of reaction.

Notable among these are asbestos and talcum powder, magnesium silicate.⁴

Kettle⁵ has produced lesions using kaolin. By analysis his specimens of kaolin were shown to contain particles of quartz and numerous fibers of sericite (potassium aluminum silicate), the majority measuring 3 microns or less.

Jones, Carleton and Haynes also came to the conclusion that kaolin is a potentially dangerous dust. Whether it is the quartz or the sericite in kaolin which is responsible for the lesions has not been unequivocally determined.⁶

However, Kettle⁵ points out, "with different forms of crystalline silica and with certain silicates essentially the same kind of lesion is produced, such modifications as occur depending on the size of the silica particles and their degree of solubility." Gardner² also agrees that the size of the particle is very important in the type and extensiveness of the lesion produced.

With this knowledge, namely that silica and certain silicates may produce a specific type of granulomatous reaction in various tissues of the body, we may now consider their effect on the gastric mucosa.

REPORT OF CASE

History.—A white man aged 37, an automobile mechanic, had abdominal pain, pyrosis, nausea and vomiting over a period of eight years. He had no permanent relief from various medications or diet. A diagnosis of duodenal ulcer had been previously made, but roentgenographic studies made subsequently were essentially negative. A later diagnosis of colitis had been made erroneously.

Physical examination revealed nothing of significance excepting epigastric tenderness.

The urine, stool, blood count, sedimentation rate and Wassermann reaction were normal. The gastric analysis revealed free hydrochloric acid 68-86 and total acid 77-102.

A gastroscopic examination was made with the 50 degree angle flexible gastroscope. The mucosa of the prepyloric

region was thickened. A gray nodular area approximately 2 cm. in diameter was present on the posterior wall of the antrum immediately distal to the angulus (incisura). This nodule was rounded and irregular; the surface was covered with numerous shiny excrescences (fig. 1).

The rugae of the midportion of the body of the stomach were hypertrophied.

Roentgen examination two days later revealed a mild degree of hypertrophic gastritis and duodenitis. The lung fields were clear.

Despite the essentially negative findings, it was thought that the long history of symptoms and the unusual gastroscopic observations were indications for surgery. A subtotal gastrectomy was done five days later.

Gross examination of the stomach after its removal showed evidence of an old healed duodenal ulcer. No lesion as described gastroscopically was seen, much to our chagrin.

The patient became asymptomatic and has remained so for over two and one-half years.

During the early postoperative period we awaited with anxiety the histologic report.

Microscopic Study.—At the base of the mucosa were a few irregularly spaced lesions of a granulomatous nature. These were made up of nodules of a definite architecture. The center of the nodule contained a large cell which was multinucleated, granular and usually fairly large. The nuclei of many of the giant cells tended to congregate about the periphery.

Encapsulating this cell was a delicate fibrous tissue which was not usually excessive in amount. Beyond the connective tissue might be seen plasma cells, lymphocytes and eosinophilic leukocytes. They were not present in sufficient numbers to constitute a real zone.

In a few of the giant cells there was foreign material (figs. 2 and 3). This varied in size and shape and was colorless and

Fig. 1.—Gray nodule covered with numerous shiny excrescences revealed by gastroscopy on the posterior wall of the antrum.

Fig. 2.—Nodular areas near the base of the mucosa. In the central part of the nodules giant cells are present, some of which surround foreign material.

refractile. Some of the particles looked like laminated spicules. Occasionally, fragmented material took a blue stain with hemotoxylin.

Fat, Masson, Kossa and acid-fast stains were negative.

Mineralogical Analysis.—A study was made of the crystals in the giant cells and in the residue of tissue after micro-incineration. They were insoluble in water, hydrochloric acid

and nitric acid. The crystals varied in size from 2 to 4 microns and belong to the hexagonal system. They were anisotropic or doubly refractive. The Becker line showed them to have a higher refractive index than Canada balsam (1.54). They had the same general morphologic appearance as the crystals present in the colloidal kaolin examined and the crystals present in the preparation used by the patient. They had the characteristics of silica.

Fig. 3.—Type of giant cell typical in silicosis surrounding foreign material. The nuclei tend to congregate around the periphery. The material is fragmented, laminated, colorless and refractile. Some of it stains blue with hematoxylin.

Preliminary Experiments on Rabbits.—With the medicament which the patient had been taking, a test experiment on rabbit stomach was undertaken. The preparation consisted of English kaolin colloidal 20 per cent and aluminum hydroxide 2.5 per cent in liquid petrolatum. We report here the findings of this "scout" experiment.

Two series of animals were tested. In the first series 2 cc. of the medication was injected into the gastric mucosa of 3 rabbits.

In series 2 a small area of the stomach mucosa of 4 rabbits was lightly curetted and the animals were fed daily a diet into which was incorporated powdered colloidal kaolin.

The rabbits of series 1 were killed at one, one and one-half and four months respectively after injection. Gross mucosal elevations or nodules were present. The microscopic examination showed groups of giant cells at the periphery of the injected material.

All the giant cells had multiple nuclei, many of which tended to group themselves peripherally or at the end of the cell like those of a Langhans cell. Colorless refractile crystals were present in many of the giant cells (fig. 4).

In the scarified series the same type of reaction was found; in fact there was greater similarity to the human case in these animals. No gross mucosal lesions were found in these animals. However, there were microscopic changes in the submucosa. Multinucleated giant cells occurred singly or in groups and were encapsulated by a fine loose connective tissue, surrounded by lymphocytes, plasma cells and eosinophilic neutrophils. Some of the giant cells contained foreign material. The most striking particles were sharp pointed clear refractile spicules.

There were giant cells about the suture material, but they were of the true foreign body type, which has little resemblance to the specific kind observed in silicosis.

The foreign material had the colorless glassy refractile appearance which characterized some of the particles of the kaolin which was examined in water suspension under the microscope for comparison.

COMMENT

Evidence has been presented to permit the reasonable conclusion that kaolin may cause a granulomatous inflammatory reaction in the stomach. This reaction is similar to that which is typical of the silica group.

Many unknown factors prevent any additional conclusions. We should like to know the conditions necessary for the silicates to produce this inflammatory reaction in the stomach. We should like to know how common this disease is. If the known reaction to silica and to silicates was accidentally discovered in this 1 case, might it not be reasonable to presume that there may be other undiagnosed cases?

We might perhaps be warranted in suggesting that patients using similar preparations be carefully observed and with the gastroscope. If symptoms should occur suggesting gastrointestinal irritation or if no relief should be obtained from the original symptoms, the possible deleterious effects of this group should be considered.

This case also illustrates the value of gastroscopy followed by tissue studies.

SUMMARY

A histopathologic and mineralogical investigation was made of the stomach of a patient who had been ingesting a preparation containing kaolin for a long period of time. Clinical and roentgen examinations revealed no gastric disease. Gastroscopy showed a prepyloric tumor, which however was not seen in the gross resected stomach. Microscopic studies proved the lesion to be a granuloma, with the type of foreign body giant cell present in the lesions of silicosis. Min-

Fig. 4.—Type of giant cell in the rabbit stomach into which the kaolin containing medication of the patient was injected is large with numerous nuclei at the periphery of the cells. Several colorless refractile crystals are seen.

eralogical studies confirmed the presence of silica in the gastric tissues.

In experimental studies on rabbits it was possible to reproduce the lesions typical of silica irritation which were similar to those found in the human case.

450 Sutter Street.

CLINICAL INDICATIONS FOR INDUCING
GASTRIC HYPOMOTILITY

FRANK E. HAMILTON, M.D.

AND

GEORGE M. CURTIS, M.D.

COLUMBUS, OHIO

The motor activity of the human stomach is of demonstrable clinical significance. This is particularly true in those patients with lesions involving viscera innervated by the extended vagi. Moreover, it appears that the clinical management of certain patients may often be aided by an increased knowledge of stomach activity.

Members of the Surgical Research Department of the Ohio State University have during the past few years investigated the motor activity of the stomach of a large number of patients under a variety of clinical conditions. Using the balloon and kymograph method, we have found that the normal motility is affected not only by disturbances in gastric physiology but also by certain pathologic lesions occurring elsewhere along the gastrointestinal tract.

More recently we have studied alterations in the motor activity which may be observed in patients pre-

Fig. 1.—Effect of atropine (given at 1) on the motility of the normal human stomach and the reversal of this effect by morphine (given at 2). Note the lowered tonus and decreased gastric activity following administration of atropine. Courtesy of Journal of Pharmacology and Experimental Therapeutics.³

sending certain common abdominal complications. Many patients complained of pain or discomfort simultaneously with obvious kymographic evidence of gastric hyper-

In an investigation of the influence of the extrinsic innervation on the motor activity of the human stomach¹ it was concluded that the vagus and splanchnic nerves carry both motor and inhibitory fibers. The effect on the stomach of stimulation of either nerve depends to a certain degree on the existing gastric tonus, although the vagus is chiefly motor while the splanchnic has chiefly an inhibitory effect. Bilateral splanchnic resection was followed by increased gastric activity, which persisted. Left subdiaphragmatic vagotomy was followed by decreased gastric activity, which persisted.

Fig. 2 (B. K., Dec. 7, 1938).—The control of postoperative "gas pains," four days after splenectomy. Severe pains were noted at the peak of the indicated contractions. Coincident with the onset of gastric hypomotility there was complete relief.

Following laparotomy the normal human stomach remains quiescent for from twenty-four to seventy-two hours.² This is followed by gastric hypermotility accompanied by abdominal distress, which is usually interpreted by the patient as "gas pains." The gastric hypermotility persists for about fourteen days postoperatively, but during the latter part of the period the patients often interpret the increased activity as hunger.

The effects of the administration of atropine, morphine and prostigmine were also determined.³ Morphine was predominantly motor. Atropine was constantly inhibitory. Morphine and atropine were mutually antagonistic, either drug counteracting the effect of the other (fig. 1). Prostigmine in the majority of instances inhibited the activity of the human stomach. Moreover, administration of prostigmine or atropine after the previous administration of either drug was uniformly followed by gastric hypermotility.⁴

With these studies as a background we are now investigating the motor activity of the human stomach during the course of common abdominal complications.

motility. Conversely, the patients ceased to complain of pain or distress when the stomach was demonstrably quiescent, whether that quiescence was spontaneous or induced by the administration of certain drugs. It is our purpose in this paper to present briefly the background of the present studies and then to draw attention to the clinical indications for inducing hypomotility of the human stomach.

From the Department of Research Surgery, Ohio State University. This investigation was aided by a grant from the Development Fund of the Ohio State University.

The Abbott Laboratories, Inc., supplied the intravenous preparations of atropine used in this investigation.

Read before the Section on Gastroenterology and Proctology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

We have continued to use the balloon and kymograph method.⁵ The motility graphs have been analyzed according to the MacQuigg classification.⁶

CONTROL OF POSTOPERATIVE ABDOMINAL CRAMPS INTERPRETED AS "GAS PAINS"

Barron, Curtis and Lauer² observed a consistent period of gastric hypermotility following laparotomy. During the early part of the hyperactive period the patients often complained of "gas pains," although in most instances there was no evidence of abdominal

Fig. 3 (K. H., Nov. 10, 1938; esophagopleural fistula; nausea six days following apical thoracoplasty; balloon introduced into stomach through gastrostomy stoma).—Control of late postoperative nausea. Continuous nausea was observed throughout the period of gastric hyperactivity. Coincident with the onset of gastric hypomotility there was complete relief.

distention. We have investigated the gastric motility in such a patient four days following splenectomy. During the period of observation the patient complained of high abdominal cramps, clinically similar to "gas pains." There was no abdominal distention, the wound was clean and there were no demonstrable postoperative complications.

The kymograph records reveal continuous high type 5 contractions. At the apex of each of the higher contractions the patient complained of a severe upper

however, that unusual gastric activities often described clinically as "reverse peristalsis" are a common finding in this condition.

Gastric activity during the course of late postoperative nausea was studied on a patient on whom a gastrostomy had previously been accomplished. Following a second operation the patient remained nauseated for six days. The balloon was introduced directly into the stomach through the gastrostomy stoma with no inconvenience to the patient. The kymograph recorded continuous irregular activity of the stomach consisting largely of type 6 motility (fig. 3). During the entire observation period the patient complained of continuous nausea.

Administration of $\frac{1}{150}$ grain of atropine intravenously was quickly followed by a diminution of gastric activity. Simultaneously with the decreased gastric activity the patient was completely relieved of the sensation of nausea and did not again complain of nausea as long as the stomach was inactive (table 2, fig. 3).

EFFECT OF DUODENAL ULCER WITH OBSTRUCTION ON GASTRIC MOTILITY

A duodenal ulcer may frequently alter the emptying time of the stomach. This is particularly true of obstructive ulcers. However, there has been but little investigation of the relation of the clinical symptoms to abnormal gastric activity in the ulcer patient.

TABLE 2.—Analysis of Gastric Motility During Control of Late Postoperative Nausea (K. H.)

Case	Investigation	Type	Length, Min.	Average, Mm.	Number of Contractions	Number of Contractions of Maximum Amplitude, Range Mm.	Maximum Intervals, Min.	Comment
Nausea 6 days post-operative 11/10/38	1. Observation	6 & 8	33	17	50	2 of 41 to 48 mm.	2	Continuous nausea
	2. Atropine $\frac{1}{150}$ grain intravenously	1 & Q	24	6	5	2 of 10 mm.	20	Complete cessation of nausea

abdominal cramp, clinically indistinguishable from a "gas pain" (fig. 2). Moreover, the intensity of the pain appeared to vary with the amplitude of the recorded contraction.

Immediate partial inhibition of gastric motility was observed following the intravenous administration of $\frac{1}{150}$ grain (0.4 mg.) of atropine. Coincidentally with the decreased gastric activity, the patient was completely relieved of the abdominal cramps and did not again complain of pain or distress during the entire period of reduced activity (table 1, fig. 2).

On this and at subsequent observations symptomatic relief of postoperative abdominal cramps interpreted as "gas pains" was effective as long as the stomach remained quiescent. This period, usually two to three hours in length, was the usual duration of the drug effect.

CONTROL OF LATE POSTOPERATIVE NAUSEA

Postoperative nausea may be immediate or late. Immediate postoperative nausea is frequently observed as the patient recovers from the effects of a general or even of a local anesthetic. It is usually a self-limited condition. Late or prolonged postoperative nausea, however, may be a serious complication and at times indicates a grave physiologic disturbance. The etiology of late postoperative nausea may be so diversified that no single mechanism may be responsible. It appears,

N. U., a white man aged 47, was admitted to the University Hospital with a partial pyloric obstruction due to a benign ulcer of the first part of the duodenum. The patient had been under medical care for the preceding twelve years. Obstructive symptoms had been present for two months before he entered the hospital. Several preoperative gastric motility investigations were accomplished. During these observations it became possible to control the symptoms of "pylorospasm." ⁷ Posterior gastrojejunostomy was then accomplished. A number of postoperative observations have been made.

During one of the preoperative motility studies the balloon was swallowed and the recording started while the patient was complaining of severe cramping epigastric pain that clinically was indistinguishable from the usual symptoms of "pylorospasm." At this time there was obvious kymographic evidence of greatly increased gastric motility, largely type 5 and 8 contractions (table 3, fig. 4).

Following the administration of $\frac{1}{150}$ grain of atropine intravenously, the stomach quickly became hypomotile with an ensuing immediate relief from the distress. Moreover, the patient did not again complain of epigastric pain as long as the stomach was demonstrably quiescent.

At the beginning of another preoperative observation the patient had no pain and was quite comfortable, and the kymograph showed but little gastric activity. Soon spontaneous gastric hypermotility became evident, and coincidentally with the greatly increased type 5 activity the patient complained

7. Hamilton, F. E., and Curtis, G. M.: The Effect of Duodenal Ulcer with Obstruction on the Motor Activity of the Human Stomach, *Rev. Gastroenterol.*, to be published.

of severe cramping pain, clinically indistinguishable from that of "pylorospasm" (table 3, fig. 5).

This period of epigastric pain associated with gastric hypermotility was of short duration and was terminated by a spontaneous remission of the increased gastric activity. Again, cessation of pain occurred simultaneously with the onset of

cystic duct and common duct. Preoperatively the patient had occasional attacks of upper abdominal pain clinically indistinguishable from biliary colic.

During such an attack the motility of the stomach was investigated.⁸ The balloon was passed without

TABLE 3.—Analysis of Gastric Motility During Control of "Pylorospasm" Due to Obstructive Duodenal Ulcer (N. U.)

gastric hypomotility and persisted as long as the stomach remained quiescent.

It was found at operation that the patient had a benign, obstructive, duodenal ulcer with a partial pyloric stenosis. Under these conditions intermittent "pylorospasm" is a common clinical finding. It is consequently possible and even probable

difficulty, and continuous type 6 activity was observed (table 4, fig. 6). This irregular type of gastric hypermotility was unchanged throughout an observation period of forty minutes, while during the entire period the patient complained of upper abdominal pain indis-

Fig. 4 (N. U., Feb. 1, 1939).—Symptomatic control of "pylorospasm" due to benign obstructive duodenal ulcer. Continuous epigastric pain indistinguishable from that of pylorospasm was noted throughout the initial period of gastric hyperactivity. Complete clinical relief was noted coincident with gastric hypomotility induced by the intravenous administration of atropine.

that the intermittent preoperative epigastric distress experienced by the patient was actually due to "pylorospasm." It cannot be concluded that the preoperative periods of spasmodic gastric hypermotility were kymographic evidences of "pylorospasm."

Biliary colic is thought to stimulate reflexly the stomach by means of the extended vagus (Barber and Stewart,⁹ McCrea¹⁰). Several investigators, Held and Roemer,¹¹ Smith and Miller¹² and others, have shown

Fig. 5 (N. U., Feb. 2, 1939).—Symptomatic control of "pylorospasm" due to benign obstructive duodenal ulcer. At the beginning the patient felt no pain. Coincident with spontaneous gastric hyperactivity the patient complained of pain indistinguishable from that of pylorospasm. This period was terminated by a spontaneous remission of gastric activity, and throughout the hypomotile period the patient felt no pain.

Since the tube length is kept constant during a given series of gastric motility studies, x-ray studies reveal that the balloon records the activity of the body of the stomach.⁵ It would consequently appear that in this investigation hypermotility of the body of the stomach occurred simultaneously with clinical evidence of "pylorospasm"; moreover, that the patient was free from pain when the stomach was demonstrably quiescent.

EFFECT OF BILIARY COLIC ON GASTRIC MOTILITY

The relation of gastric motility to biliary colic was studied on a patient who at subsequent operation was shown to have cholelithiasis involving the gallbladder,

that disease of the gallbladder, and in particular cholecystitis with cholelithiasis, stimulates gastric activity. The subjective pain in this instance may not have been

due to gastric hypermotility; nevertheless, the motility of the stomach might be an index of the relative activity of another organ having a similar nerve supply.

CONTROL OF CONTINUOUS NAUSEA AND REGURGITATION ASSOCIATED WITH PARTIAL OBSTRUCTION OF THE STOMACH DUE TO AN ADVANCED CARCINOMA

W. C., a white man aged 70, was admitted to University Hospital complaining of continuous nausea and regurgitation, inability to retain solids or liquids, loss of weight and general

It was found necessary to administer $\frac{1}{400}$ grain (0.6 mg.) of atropine intramuscularly before the patient could swallow the balloon to begin the motility investigation. Thirty minutes later he swallowed the balloon easily, and the kymograph then revealed tremendously increased gastric activity, type 8 associated with continuous nausea and regurgitation (table 5, fig. 7).

An intravenous injection of $\frac{1}{150}$ grain (0.4 mg.) of atropine was followed by little change in the hyperactivity of the stomach or in the clinical symptoms. Again $\frac{1}{150}$ grain of atropine was administered intravenously and was followed by decreased gastric activity associated with considerable clinical relief.

It should be noted that no results were observed until a total of $\frac{1}{43}$ grain (1.5 mg.) of atropine had been administered within a relatively short period of time. Finally the cumulative effect of this large amount of atropine was followed by greatly decreased type 1 motility, and for as long as the hypomotility continued the patient was quite comfortable. When the hyperactivity of the stomach was controlled by the adminis-

Fig. 6 (N. K., Feb. 6, 1939).—Symptomatic control of biliary colic due to cholecystitis with cholelithiasis. Fig 8 (B. H.).—Control of the abdominal discomfort observed in certain patients with hypothyroidism. During the period of gastric hyperactivity the patient complained of epigastric pain, with severe cramps at the apex of the indicated contractions. When the stomach was quiescent the patient felt no pain. This was true whether the gastric quiescence was spontaneous, as in the first graph (June 20, 1939), occurred following administration of atropine, as in the second graph (June 21) or was observed following adequate thyroid and iodine therapy for the control of hypothyroidism, as demonstrated in the third graph (August 2). (Courtesy of the Journal of Clinical Endocrinology.¹³)

THE RELATION OF GASTRIC MOTILITY TO HYPOTHYROIDISM

Gastrointestinal symptoms may occasionally be observed in certain patients with hypothyroidism. The discomfort usually consists of abdominal pain for which no organic basis can be demonstrated. The pain is of varying degree and appears to be associated with hyperactivity of portions of the gastrointestinal tract which are innervated by the extended vagus. The gastric motility has been determined in several such patients presenting proved hypothyroidism. The following case is typical:¹³

B. H., a white woman aged 41, was admitted to University Hospital complaining of constipation and frequent attacks of epigastric pain, variable in onset, duration and intensity. Investigation failed to reveal any organic basis for the pain. Laboratory studies revealed low blood iodine determinations and decreased basal metabolic rates, which along with the clinical findings was interpreted as evidence of hypothyroidism.

A motility investigation revealed irregular gastric hyperactivity, type 5, associated with constant epigastric pain plus colic-like epigastric cramps at

tration of adequate amounts of atropine, the patient was able to swallow and retain liquids.

By this means the patient was kept fairly comfortable throughout the duration of his period of hospitalization.

the indicated contractions (table 6, fig. 8). On the following day the kymograph recorded constant irregular hyperactivity associated with colic-like epigastric pain. Following adminis-

¹³ Hamilton, F. E.; MacQuigg, R. E., and Curtis, G. M.: The Gastric Motility in Certain Patients with Thyroid Deficiency, *J. Clin. Endocrinol.* 1:24 (Jan.) 1941.

tration of $\frac{1}{160}$ grain of atropine intravenously there was immediate cessation of gastric hypermotility with simultaneous cessation of the epigastric pain. The patient was then treated for hypothyroidism by the administration of desiccated thyroid and iodine.

Six weeks later, following a satisfactory clinical response to this treatment, investigation revealed a normal basal metabolism plus normal gastric motility. Moreover, the patient had ceased to complain of abdominal pain (table 6, fig. 8).

RELATION OF GASTRIC MOTILITY TO THE SYMPTOM COMPLEX KNOWN AS "VAGOTONIA"

Rather frequently patients are seen who are classed clinically as neurotic. In certain of these persons investigation will reveal that the discomfort of which they complain appears to be limited to the distribution of the extended vagus. In some of these no organic basis can be demonstrated to account for the pain. To this delimited group of patients the term "vagotonia" has been applied.¹⁴ Admittedly the term "vagotonia" is, indeed, inclusive, yet clinically it appears to apply well in this symptom complex. The alterations in gastric motility have been investigated in a number of such patients, as is exemplified in the following case:

F. H., a white housewife aged 46, was admitted to University Hospital complaining of dull, more or less constant epigastric pain. Thorough investigation failed to reveal an organic basis for the pain. There was no evidence of hypothyroidism. At the beginning of a motility study the patient stated that she was quite comfortable and had no pain. However, the kymograph recorded greatly increased gastric activity, type 7. After an interval a spontaneous elevation of tonus was observed, associated with the same type of gastric activity, and at once the patient complained of constant epigastric pain. Administration of atropine was followed by a lowered tonus, decreased gastric activity and simultaneous cessation of pain (table 7, fig. 9). Throughout the investigation the patient did not complain of epigastric discomfort when the stomach was quiescent.

CONCLUSIONS

By the balloon and kymograph method hypermotility of the human stomach has been demonstrated during the clinical appearance of "gas pains," late postoperative nausea, "pylorospasm" due to obstructive duodenal ulcer, biliary colic, the nausea and regurgitation associated with advanced carcinoma of the stomach, certain instances of hypothyroidism and "vagotonia."

In all gastric hypermotility occurred simultaneously with the varying degrees of clinical distress or discomfort. Moreover, the patients ceased to complain of pain or discomfort when the stomach was quiescent. Whether the gastric hypomotility was spontaneous or induced by the administration of atropine made no apparent difference. At the onset of hypomotility the patients ceased to complain of distress.

From these clinical studies it appears that the motility of the human stomach may be regarded as an indicator of certain types of abnormal activity of the gastrointestinal tract. Control of the gastric hypermotility in such instances will often simultaneously control the clinical symptoms associated with the primary condition.

CHRONIC ALCOHOLIC GASTRITIS

EVALUATION OF THE CONCEPT, WITH GASTROSCOPIC STUDIES IN ONE HUNDRED CASES

LEONIDAS H. BERRY, M.D.

CHICAGO

Widespread drinking of alcoholic beverages goes back at least to the epicures of antiquity. Laymen and physicians alike have conjured up in their minds a frightful picture of the ravages of alcohol on the lining of the human stomach. Thirty or forty years ago gastritis, and especially alcoholic gastritis, was widely diagnosed on the basis of the character of the secretions removed by the stomach tube. The presence of a large amount of mucus was the essential factor in the diagnosis of "gastric catarrh," or chronic gastritis. In later years gastritis was regarded as a loose term which included many digestive symptoms. Chronic inflammation of the stomach as a definite organic entity was regarded as rare. For a long time it was taught, and in some centers it is still taught, that the one excellent example of chronic gastritis is that due to the chronic use of alcoholic beverages.

Within the last few years, with the aid of the flexible gastroscope, chronic gastritis has been shown to be widespread and to be an important organic entity in persons who do not use alcoholic beverages at all. The statistics of Schindler¹ on a group of 1,000 persons with dyspepsia in America and on a smaller group in Germany showed 41 and 45 per cent, respectively, with chronic gastritis. My recent statistics² based on 800 gastroscopic examinations showed 43.3 per cent of persons with dyspepsia in the gastrointestinal clinic of the Provident Hospital to have chronic gastritis. In none of the groups mentioned was there a significant number of chronic alcoholic addicts. It has become evident to all gastroscopists that certainly persons other than alcoholic addicts may have chronic gastritis. The question therefore arises: What really is the role of alcohol in chronic gastritis, in the light of the more recent advances in this field?

In order to reevaluate the clinical concept chronic alcoholic gastritis, I first reviewed the literature for convincing evidence of experimental alcoholic gastritis in animals and postmortem evidence of the disease in man. Secondly, I undertook to select a fairly large group of persons who unquestionably were alcoholic addicts, to examine them gastroscopically and to correlate certain clinical data with the gastroscopic picture.

EXPERIMENTAL ALCOHOLIC GASTRITIS

Friedenwald³ in 1905 fed 50 per cent alcohol to a large group of rabbits for several weeks and found that he could not consistently produce gastritis. Fahr⁴ in 1911 attempted to produce irritation gastritis in 5 rabbits. He found mild hyperemia, but the gastric tissue was microscopically normal. One of the most

a great increase in mucus. A biopsy and histologic sections showed acute inflammation. During a two month rest period the mucosa returned to normal, grossly and microscopically. Eight months after the termination of the alcohol feeding the animal became progressively more debilitated and died. Autopsy showed extensive atrophic gastritis. While Thomsen was inclined to interpret the profound atrophy as due to the chronic effect of alcohol, I feel that any chronic debility is likely to be associated with atrophic changes in any organ and that one could not justifiably conclude that the atrophy in the dog's stomach was the direct effect of alcohol.

PATHOLOGISTS' CONCEPTIONS

No pathologic picture has been generally accepted among pathologists as characteristic of alcoholic gastritis. Some investigators have stated that alcoholic gastritis is not infrequently seen at autopsy. Fahr,⁴ for example, stated that gastritis is often associated with so-called alcoholic cirrhosis but that there are many cases of cirrhosis without gastritis. He admitted, however, that the congestion due to obstruction of the portal system rather than the alcohol directly may be responsible for the gastritic changes. Henning⁶ stated that concentrated alcohol solutions damage the glands of the stomach but that weak solutions produce hypersecretion without inflammation. Hirsch⁷ examined at autopsy the stomach in 21 patients who had been heavy drinkers. Nine had died of acute delirium tremens.

7 Hirsch, E. F. The Gastric Mucosa in Delirium Tremens, *Arch Int Med* 17: 354 (March) 1916.

Zenker's fixing fluid was introduced into the stomach immediately after death in every case, and sections from all parts of the stomach were studied microscopically. These sections were compared with the original sections of the anatomist Bensley,⁸ from which he described the normal microscopic picture of the adult stomach. The studies of Hirsch revealed scattered petechial hemorrhages but no consistent gastritis.

GASTROSCOPIC STUDIES

The earliest description of the living human stomach after the ingestion of alcohol was that of Beaumont⁹ in 1833 concerning the fistulous stomach of Alexis St. Martin. The picture was essentially that of erythema and increase in the secretion of mucus. Only one article written since the advent of the flexible tube gastroscope could be found in the foreign literature, and none in the American literature, on the gastroscopic appearance of the stomach in a group of persons with severe chronic alcoholism. A preliminary report² of my alcoholic studies was made before the Chicago Society of Internal Medicine, Feb. 24, 1941. In 1936 Villaret, Moutier and their associates,¹⁰ of Paris, studied 45 chronic alcoholic addicts gastroscopically. Each had polyneuritis and an enlarged and painful liver. Of the 45, 20 had also had ascites. All had digestive symptoms, such as increasing anorexia, bilious vomiting, constipation and diarrhea and distress after meals. Gastroscopically, all but 1 showed chronic atrophic gastritis. Fifteen patients came to autopsy, and the diagnosis of atrophic gastritis was confirmed.

My series consisted of 100 ambulatory alcoholic addicts. None of them had an enlarged or painful liver or ascites. Sixteen came to the clinic because of some type of digestive distress. The remaining 84 subjects did not seek medical aid but were induced to come to the clinic only for this study. (They are termed nonclinic addicts hereafter.) They were unattached men who lived for the most part in "flophouses" and

drank in bouts of several days, remained sober for a few days and became drunk again. Others drank continuously each day. Most of them had been drinking for fifteen or more years. They consumed such varied beverages as straight whisky, beer, rubbing alcohol, home-brew, automobile antifreeze and bay rum. Whisky drinkers consumed 2 to 3 pints (a pint is 0.47 liter) per day. Some addicts drank a half gallon of wine or as much as a gallon (3.7 liters) of beer. Ninety per cent of the addicts were also heavy smokers. They were tremulous when not drinking, and many of them had delirium tremens. Cramps in the limbs rather than frank polyneuritis occurred as a rule, and hallucinations were present in some cases. The percentage of positive Wassermann reactions was not higher than that for the general population. Seven of 88 addicts had incipient tuberculosis. Nearly one half of the subjects had low grade anemia, and most of them had severe vitamin C and nicotinic acid deficiencies, as measured by the plasma ascorbic acid levels and by the porphyrin bodies in the urine. Fractional histamine tests showed achlorhydria in 7 of 56 cases. Four fifths of the men ate little or no food while drinking.

The gastroscopic picture of the 84 nonclinic alcoholic addicts was at first surprising because of the absence

in the clinic was of the atrophic type.² Further, experiments strongly suggest that vitamin B complex deficiencies constitute one cause of atrophic gastritis.² Perhaps the more or less constant local hyperemia in the stomach of the alcoholic addict supplies adequate nutrition to the mucosal cells and thereby tends to prevent atrophy.

The 16 clinic alcoholic addicts drank at greater intervals and consumed smaller quantities of alcohol than the nonclinic addicts. Some had stopped drinking entirely for considerable periods. These patients, who were also in poor vitamin nutrition, showed a high percentage of atrophic gastritis.

SYMPTOMS

My study reveals that the heavy-drinking, nonclinic alcoholic addicts, who also smoked almost incessantly, usually had no distress after meals. In striking contrast to the clinic patients with chronic gastritis, the alcoholic addicts could tolerate all kinds of meats, baked or fried, and foods such as chile con carne and barbecue. They used large quantities of such condiments as red pepper and horse radish. Their bowels moved once or twice a day, or they had mild diarrhea rather than the constipation seen so frequently in persons with non-

Fig. 1.—Gastroscopic view: mild chronic superficial gastritis (alcoholic type).

Fig. 3.—Gastroscopic view: before therapy.

Fig. 4.—View after therapy.

of gross abnormalities comparable to those seen in nonalcoholic gastritis. The one characteristic seen in all cases was a moist and glistening mucosa with increased highlights. The color was usually a uniform, evenly distributed, orange-red, which was described in 35 per cent of cases as indicative of mild hyperemia (figs. 1 and 2). The color was like that in active physiologic hyperemia rather than like the mottled or deeper red seen sometimes in chronic nonalcoholic gastritis. The disease in these cases was classified as mild chronic superficial gastritis (table 2). In 17 per cent of the cases it was classified as moderate chronic superficial gastritis, because in addition to the moist, glistening appearance the mucosa was a moderately deeper orange-red than in the first group. There were also deposits of translucent, gelatinous, gray mucus or porcelain-like white mucus between the folds in some cases. In still other cases there were scattered petechial or ecchymotic hemorrhages and tiny superficial gray erosions. The folds in some cases appeared swollen. In 26 per cent of the series the mucosa was classified as normal, but in the 35 per cent in which the disease was classified as mild superficial gastritis the mucosa presented only a little difference in color. Occasional petechial hemorrhages, erosions or small bits of mucus constituted the principal variations from normal. The low incidence of atrophic gastritis associated with widespread hypovitaminosis and subnutrition was interesting in the light of my experiences with patients with non-alcoholic gastritis. Fifty-seven per cent of all gastritis

alcoholic gastritis. The morning nausea, or tendency to vomit, which some addicts had was prevented by what they referred to as the "eye opener," usually about a half pint of whisky. On the other hand, most of the clinic alcoholic addicts complained of intermittent dull aching around the navel, epigastric fullness, occasional nausea or vomiting. Thus, in order of the severity of their symptoms the group with nonalcoholic gastritis ranked first, the clinic group of alcoholic addicts second and the heavy-drinking, nonclinic alcoholic addicts third.

THERAPEUTIC TESTS

In order to test whether mild inflammatory changes actually occurred, 17 chronic alcoholic addicts were given vitamin B complex and then examined gastroscopically (table 3). These tests are not reported as an experiment in therapy. Properly controlled studies along this line are now being carried out. Observations were made periodically, and the periods of therapy varied from seven days to several months. Fourteen of the 17 subjects were treated in the hospital for two to four weeks, receiving no alcohol. Gastroscopy was done every seven days. Two patients had twelve and thirteen gastroscopic examinations, respectively, over a period of three years, with intermittent courses of therapy with the vitamin B complex. After two or more weeks the gastric mucosa of the hospital-controlled patients showed a slight decrease in the orange-red and a lessening of the moist, glistening appearance (figures 3 and 4 show views of the stomach before and after therapy).

Several patients were kept on therapy a few weeks after hospitalization, during which time further reduction of the mild hyperemia and of the moist, glistening character was evident. The hyperemic color disappeared more rapidly than the moist, glistening character of the mucosa. In a few anemic patients with mild superficial gastritis the mucosa became a pale pink consistent with their reduced hemoglobin level after a few weeks of therapy. In some instances superficial gastritis superimposed on atrophic or on hypertrophic gastritis disappeared, leaving the underlying gastritic changes more prominent. After long periods of therapy atrophic changes tended to disappear also.

TABLE 3.—*Gastroscopic Diagnosis Before and After Vitamin B Complex Therapy for Seventeen Alcoholic Addicts*

Patient	Diagnosis Before Therapy	Diagnosis After Therapy	Follow-Up Period	No. of Gastroscopies
1	Superficial and hypertrophic	Superficial (mild)	1 wk.	2
2	Superficial (mild)	No superficial	1½ wk.	2
3	Superficial (mild)	Superficial (mild)	2 wk.	3
4	Superficial (moderate)	Normal mucosa	2½ wk.	3
5	Superficial (moderate)	Superficial (mild) and hypertrophic	2½ wk.	4
6	Superficial (mild)	Practically normal mucosa	2½ wk.	3
7	Superficial (mild)	Normal mucosa	3 wk.	3
8	Normal mucosa (increased highlights)	Normal mucosa	7 wk.	4
9	Superficial	No superficial; more hypertrophic	7 wk.	5
10	Atrophic	Atrophic (no change)	1 mo.	3
11	Superficial and atrophic (slight)	No superficial or atrophic (but localized hypertrophic)	2½ mo.	4
12	Superficial and atrophic	Normal mucosa	4 mo.	4
13	Atrophic	Atrophic (no change)	4 mo.	4
14	Superficial and atrophic	Atrophic (slight); no superficial	7 mo.	3
15	Superficial and hypertrophic	No superficial; hypertrophic	11 mo.	6
16	Superficial and atrophic (severe)	Mucosa practically normal	3 yr.	12
17	Superficial and atrophic	Gastritis disappeared and reappeared	3 yr.	13

SUMMARY AND CONCLUSIONS

1. The evidence from the literature on attempts to produce chronic alcoholic gastritis in experimental animals shows that in some instances a transient superficial type of gastritis has been produced but that in many other instances no gastritis has been produced.

2. Pathologists have supplied no evidence in the literature of unequivocal chronic gastritis due to alcohol. One well controlled observation (Hirsch⁷) demonstrated frequent gross and microscopic petechial or ecchymotic hemorrhages but no inflammation.

3. No previous gastroscopic study of alcoholic addicts has appeared in the American literature. The one report in the foreign literature, on 45 patients, describes extensive atrophic gastritis, which in my opinion was probably not due to alcohol directly.

4. Gastroscopic studies on 100 persons with unquestionable chronic alcoholism of long standing showed 30 per cent not to have gastritis, 35 per cent to have mild chronic superficial gastritis (with a gastric mucosa only slightly different from normal) and only 35 per cent to have unequivocal chronic gastritis.

412 East Forty-Seventh Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. COHN, WHITE AND WEYRAUCH, DRS. HAMILTON AND CURTIS AND DR. BERRY

DR. SIDNEY A. PORTIS, Chicago: It is through such contributions as Dr. Berry's that we are able to reconstruct many of our ideas concerning changes produced in the stomach of patients with chronic alcoholism. All of us have thought in the past that patients with chronic alcoholism usually exhibit chronic gastritis. Many are not acquainted with the type of these patients; if one was to walk along West Madison Street in Chicago one would see the type of derelicts that were used in this experiment. If these individuals, with their debility and inanition, cannot acquire chronic gastritis after the alcohol they take, I doubt whether any one could. It is evident that we must break down some of our older concepts of disease and change some of the nomenclature. We used to talk about alcoholic cirrhosis of the liver and similarly about alcoholic polyneuritis, and yet none of us today believe that alcohol in itself is the cause of either of these two pathologic conditions. Dr. Berry produced such unusual changes in the stomach with the use of vitamin B therapy. He is conducting an excellent clinic in gastroenterology at the Provident Hospital in Chicago.

DR. DAVID J. SANDWEISS, Detroit: Drs. Hamilton and Curtis showed that hypermotility of the human stomach is associated with pylorospasm due to obstructive duodenal ulcer. I should like to ask whether hypermotility is also found associated with the epigastric distress of uncomplicated duodenal ulcer. Patterson and I have found (in a limited number of patients so far studied by the balloon-kymograph method) that epigastric pain due to uncomplicated duodenal ulcer may be present without evidence of gastric hypermotility. We have also found that the Sippy powder solution given to a patient with an uncomplicated duodenal ulcer does not inhibit gastric motility either in frequency or in amplitude of contractions or in the duration of the period of activity. Yet this solution usually gives instantaneous relief of epigastric ulcer pain. It would appear, therefore, that ulcer pains may be present without evidence of hypermotility; also that relief of epigastric distress is not necessarily associated with hypomotility. Apparently, gastric motility is not the only factor involved in epigastric or abdominal pain. How would the authors explain epigastric pain due to ulcer when normal gastric motility is present? In 1916 Ginsburg, Tumpowsky and Hamburger found that "with the onset of strong contractions the patients complained of symptoms varying in interpretation from a feeling of fullness and tightness to severe epigastric pain. The sensation nearly always came on when the contractions had reached their height." Carlson confirmed these findings but added "These contractions are not stronger or more prolonged than the stomach contraction felt as ordinary hunger pangs on days when the subject has no ulcer symptoms." I agree with Drs. Hamilton and Curtis that gastric hypermotility may be associated with certain abdominal or epigastric pains; however, one might question the conclusions drawn from the data presented. Gastric motility is modified by many afferents other than those coming from the gastrointestinal tract, such as somatic pain, physical exercise, emotional states or a cortical lesion. From a practical therapeutic point of view I believe that, while the correlation of gastric hypermotility and the organ primarily involved is of interest, therapy should be directed toward the primary focus rather than toward the hyperactive stomach. Control of the former will invariably relieve the symptoms associated with the latter.

DR. HOWARD T. KARSNER, Cleveland: The report of Drs. Cohn, White and Weyrauch adds information on an additional hazard in the use of preparations containing kaolin. Further observations are required to determine how often this complication occurs. It is possible that the patient suffered at one time from peptic ulcer, which might have permitted entry of the particulate matter into the mucosa and submucosa. It is difficult to understand the presence of the kaolin in the wall of the stomach unless there had been an interruption of surface continuity. The microscopic appearance is characteristic of the so-called pseudotubercle or foreign body tubercle. The giant cells differ from typical Langhans cells of tuberculosis in that although the nuclei are peripherally situated they are not arranged with the long axis radial to the center of the cell.

Care should be exercised not to confuse these and comparable lesions with true tubercles or miliary gummas. The experimental confirmation of the production of similar granulomas in the wall of the rabbit's stomach, together with the microchemical and microcrystallographic studies, leaves no reasonable doubt that the human lesion was due to the medicament. Of interest is the fact that polymorphonuclear leukocytes appear to have played little or no part in the reaction, especially in view of the observations of McCutcheon, Coman and Dixon on negative chemotropic effects of kaolin. As indicated by Dr. Cohn and his co-workers, information about the pathologic effects of deposits of silica is extensive. It is now known that the size or shape of the particles is of little significance in determining the lesion. Furthermore, as shown by King and Belt, the lesion is not proportional in size or character to the amount of silica within it. The lesions in the lung and spleen in silicosis are now believed to be due to silicon dioxide. The peritoneal lesions following the introduction of glove powder are evidently due to magnesium silicate. The authors have shown convincing evidence of the action of hydrated aluminum silicate in the human case and in the rabbit. The lesion differs microscopically from the usual silicotic nodule in the lung, because in the latter there is a far greater disposition to fibrosis and hyalinization than is true of the kaolin lesions. This difference may be due to variations in response to the salts present or may be due to the manner in which the lung and the wall of the stomach react. Important as is this contribution, conclusions cannot yet be drawn as to the effects of the lesion on function of the stomach.

DR. ROBY JOHN F. RENSHAW, Cleveland: I should like to ask Dr. Hamilton how long the effect of intravenous atropine lasted. With the dosage that Drs. Hamilton and Curtis gave intravenously did those patients suffer the same side effects that patients given larger doses subcutaneously or orally might suffer? There was an important point in the paper of Drs. Cohn, White and Weyrauch: the lesion was seen gastroscopically but not radiologically and not even in the gross specimen. The value of gastroscopy in this case cannot be questioned. The remarkable thing is Why don't all the people who take alcohol acquire gastritis? There must be other conditions necessary for the gastritis to develop, even though some irritant constantly insults the gastric mucosa. I shall be interested in Dr. Berry's future reports, hoping that he will observe these patients and others over a longer period of time and correlate not only the effects of alcohol but also environmental and social factors.

DR. HERMAN J. MOERSCH, Rochester, Minn.: Drs. Cohn, White and Weyrauch are to be congratulated on their ability to distinguish gastroscopically such a small lesion as a granuloma. It is especially commendable that they followed up their gastroscopic observations with experimental studies. Their experimental observations again confirm the clinical observations of Beaumont, Rogers and, more recently, Berry that the gastric mucosa under certain conditions, when exposed to an irritant, either chemical or traumatic, may give rise to an inflammatory reaction. This reaction is demonstrated easily by the local application of acetylsalicylic acid to the gastric mucosa. In some cases a region of inflammatory reaction will appear in the gastric mucosa where the acetylsalicylic acid is in contact with it, whereas in other cases such a reaction does not take place. Of even greater significance is the fact that, in those cases in which acetylsalicylic acid gives rise to an inflammatory reaction, such an inflammation is not necessarily associated with clinical symptoms. It is interesting to speculate as to whether persistent irritation of the gastric mucosa will lead eventually to further serious organic disease. This question, of course, is something that cannot be answered satisfactorily at the present time. I am especially interested in the histopathologic data concerning the changes produced in the gastric mucosa by the use of silicates. I cannot agree with the authors that both silica and silicates produce a characteristic microscopic picture in the gastric mucosa. Most observers are in agreement that silica will produce typical changes in tissue. Silicates, however, like any other foreign substance, will produce inflammatory changes but will not, as a rule, produce the characteristic fibrous nodules. It is true that asbestos and probably

sericite may produce changes in tissue closely simulating those produced by silica. Although the distinction between the reaction produced in the gastric mucosa by silica and that produced by silicates may seem only of academic interest, it may be of considerable importance from a prognostic point of view.

DR. WALTER L. PALMER, Chicago: I wish to speak of the paper of Drs. Hamilton and Curtis. I found it difficult to orient myself with regard to the normal contractions. One is in the habit of seeing the so-called types 1, 2 and 3 hunger contractions, with occasional tetanic contractions, followed by periods of quiescence in a normal stomach. I am more accustomed to seeing these contractions measured with a water manometer and perhaps that is the reason it was difficult for me to orient myself. I wondered if they had taken sufficiently into consideration the differences which occur from individual to individual, that is, the normal individual and also the variations which occur with advancing age. Of course, the effect of atropine on gastric motility and on intestinal motility is well recognized. My experience has been the same as theirs in that intravenous injection of atropine does stop the contractions abruptly, but not for a very long time. Dr. Sandweiss has emphasized the fact that the seemingly definite correlation between these gastric contractions and the pain of the patient does not necessarily prove that the pain arose in the stomach. For instance, I have taken contraction tracings from the intestine and from the stomach simultaneously and found that there isn't very much lag in the intestinal contractions as compared with the gastric contractions; therefore it seems to me quite possible that the gas pains of which the patient complained really arose in the intestine rather than in the stomach, and it would seem to me quite likely, as Dr. Sandweiss suggested, that in the case of biliary colic the pain actually arose in the biliary tract rather than in the stomach. With regard to the pain of pylorospasm, Dr. Hamilton, I wish you would tell us how you diagnose that clinically. I doubt if one can.

DR. ALLAN L. COHN, San Francisco: The question as to how this material got into the mucosa, of course, occurred to us at once. We still do not know. We doubt, however, Dr. Karsner, that this man had an additional previous ulcer in this portion of the antrum where we saw the nodule. There was a diffuse infiltration of this material as far as the pylorus. We saw more areas microscopically than we did macroscopically. In the literature on the granulomas caused by talcum powder there is a report by Antopol, who demonstrated that, by rubbing talcum powder on the serosal surface of an appendix, crystals of magnesium silicate can be seen to have deeply penetrated the tissues. It is probable that this material likewise entered the gastric mucosa and caused this tumor by friction, and penetration into these scattered areas. Now, Dr. Moersch, in our paper we made no fine distinction between silica or silicates as the causative agent. We now understand from the manufacturers of the particular agent which the patient had been taking that there is a contamination in the so-called colloidal material of about 2 or 2.5 per cent of crystalline material. It is quite probable that the material consists of both the silicate and silica. The point of the paper, however, remains the same whether the foreign material is silica, silicate or both. In presenting this first case the purpose was to raise the question as to the possible irritative effect not only of kaolin but also of the whole silicate group now used in gastroenterologic practice. Our purpose was also to stress the value of gastroscopy, especially when followed by microscopic studies.

DR. FRANK E. HAMILTON, Columbus, Ohio: Our present purpose is to obtain symptomatic relief from the type of abdominal distress associated with gastric hypermotility. We have repeatedly demonstrated that atropine is the most effective drug for this purpose. There are variations in the normal motility of the human stomach. This has been emphasized by Dr. A. J. Carlson and by Dr. L. E. Barron, who was assisted by Dr. Carlson in developing the method we now use. The lantern slide used to demonstrate normal human gastric motility is from Barron's work. The variations presented by that slide are quite different from the gastric hypermotility demonstrated by the present investigation. None of the patients just presented could be classed as "normal" at the time they were studied. All of them presented a single, proved clinical entity such as

biliary colic or "pylorospasm." In such clinical conditions we have shown that the normal gastric motility is greatly altered and often resembles the Carlson type 2 or even type 3. It is not our contention that the pain necessarily originates in the stomach. Moreover, we have not stated that gastric hypermotility must be demonstrated at the time the patient experiences the sensation of pain. On the contrary we have endeavored to emphasize that when, under certain conditions, a patient complains of this type of abdominal pain we can demonstrate simultaneous gastric hyperactivity. This is particularly true of lesions involving viscera innervated by the extended vagi, as for example cholelithiasis or "pylorospasm" due to obstructive duodenal ulcer. In such instances our clinical diagnosis depends on proving at subsequent laparotomy the existence of a benign, obstructive ulcer of the duodenum. Under such conditions patients occasionally develop preoperatively certain epigastric symptoms to which the general term "pylorospasm" has been applied. At the same time we can usually demonstrate gastric hypermotility. Moreover, if the abnormal gastric hyperactivity associated with this condition can be returned to normal, the patient is simultaneously relieved of the epigastric distress. We have as yet been unable to demonstrate consistent alterations in gastric motility in patients presenting nonobstructive duodenal ulcers. We still maintain our basic conclusions that the motility of the human stomach may be regarded as an indicator of certain types of abnormal activity of the gastrointestinal tract and that control of that hypermotility will usually simultaneously control the associated symptoms.

SULFONAMIDES IN THE TREATMENT OF ERYSIPELAS

ROBERT E. SHANK, M.D.

RICHARD W. MAXWELL, M.D.

AND

GEORGE S. BOZALIS, M.D.

ST. LOUIS

Erysipelas, a common bacterial infection of the skin caused by the hemolytic streptococcus, is a disease entity particularly suitable for the trial of new chemotherapeutic agents. This is true because the location of the lesion makes it available for accurate study and because methods of treatment prior to the use of sulfanilamide were notably unsatisfactory.¹ In 1936, shortly after the introduction of the sulfonamide drugs, Meyer-Heine and Huguennin² reported 150 cases of erysipelas treated with sulfanilamide producing a rapid fall in the temperature and subsidence of the local lesion within forty-eight hours. There were no deaths and few complications. Breen and Taylor³ in 1937 obtained equally gratifying results in 35 cases treated. There were two deaths in this series. Subsequent publications by Snodgrass and Anderson,⁴ Hageman and Blake,⁵ Nelson, Rinzler and Kelsey⁶ and Hoyne, Wolf and Prim⁷ state that the sulfonamide drugs are used with great benefit in the treatment of erysipelas, stopping the progress of the lesion, decreasing the number of days of fever and

the length of hospital stay, reducing the incidence of complications and lowering the mortality rate.

Foley and Yasuna,⁸ in a recent report of 80 cases treated with sulfanilamide with an equal number of untreated control cases, gave comparative results of average duration of fever of two and ninety-four one-hundredths days in treated cases and four and seventy-four one-hundredths days in the controls. The complication rate was 9 per cent in those receiving sulfanilamide and 22.5 per cent in those not getting the drug. Mortality rates were 2.5 per cent in the treated group and 10 per cent in the control series. However, Rantz and Keefer⁹ considered the duration of the disease shortened only if sulfanilamide was given before the third day of the disease. They found no difference in the number of complications or in the number of relapses seen in treated cases and untreated controls.

At the St. Louis Isolation Hospital 165 patients were treated for erysipelas during the two year period between January 1939 and January 1941. All these received sulfanilamide or one of its derivatives in comparable dosage. Each patient in this series was seen by one of us. A somewhat detailed study of this group and the results of therapy is to follow.

Sulfanilamide was the chemotherapeutic agent used in 102 cases, sulfamethylthiazole in 29 cases, and a new acyl derivative of sulfanilamide, S-22, or sulfabenameide,¹⁰ was given in 34 instances. The dosage of these drugs was as follows:

Two-tenths Gm. per kilogram of body weight up to a maximum of 8 Gm. divided into six equal doses and given every four hours for the first twenty-four hours.

Fifteen one-hundredths Gm per kilogram of body weight to a maximum of 6 Gm. in the second twenty-four hours.

One-tenth Gm per kilogram of body weight to a maximum of 4 Gm daily for the duration of the hospital stay.

In addition to chemotherapy, cold boric acid packs were used routinely to relieve pain and discomfort. To prevent recurrence of the lesion, patients were hospitalized from seven to ten days and kept on drug therapy the entire time.

The age and sex distribution with mortality figures for each group are presented in table 1. It will be noted that the majority of these patients were over 40 years of age. It is well understood that erysipelas is especially fatal to the aged and to very young infants. In this series there were only 4 patients under 2½ years of age. Two of these infants, however, 9 months and 3 months of age, had extensive erysipelas that responded promptly to drug therapy.

There were 5 deaths in the group of 165, a mortality figure of 3 per cent. This compares with mortality rates of from 8 to 12 per cent before the use of sulfanilamide as reported by others.¹¹ Necropsies were done in 4 of the fatalities. In each instance there were complicating disease processes. These are listed in table 2.

Blood concentrations of the drug used for these patients varied between 8 and 16 mg. per hundred cubic centimeters. In each instance the local lesion was seen to regress with the treatment outlined. In case 3 the blood culture showed growth of the hemolytic streptococcus on entry but subsequent cultures produced no

to the complications of degenerative disease that had not responded to the usual modes of therapy. Four of the deaths occurred in the group of 102 patients who were treated with sulfanilamide, a mortality rate of 3.9 per cent. One death among 29 patients getting sulfamethylthiazole gave a 3.4 per cent mortality for this drug, while no fatalities have developed in the sulfabamide treated series of 34 patients.

Of the 160 patients treated successfully, spread of the lesion was never noted after the first thirty-six hours of treatment. In general the erythema and induration were definitely subsiding after forty-eight hours, although some brawniness was present for from five to seven days.

In 84 cases with initial fever the temperature was normal within twenty-four hours after beginning drug therapy and remained so throughout hospitalization. Fever persisted for forty-eight hours in 49 patients, for seventy-two hours in 12, and in 4 patients for as long as four days. Thus fever persisted longer than forty-eight hours after treatment was begun in only 16 cases, or in 9.7 per cent of cases treated.

TABLE 2—Case Summaries of the Five Fatalities

Case No., Age	Color, Sex	Complicating Diseases	Drug Used	Autopsy
1 62	White ♂	Chronic nephritis, bronchopneumonia	Sulfanilamide	Yes
2 63	White ♂	Aortic aneurysm, degenerative heart disease, cardiac decompensation	Sulfanilamide	Yes
3 54	White ♂	Degenerative heart disease, auricular fibrillation, cardiac decompensation	Sulfamethylthiazole	No
4 63	White ♂	Degenerative heart disease, bacillary glomerulonephritis, right	Sulfanilamide	Yes
5 62	White ♂	Acute duodenal ulcer, massive gastrointestinal hemorrhage, degenerative heart disease	Sulfanilamide	Yes

Only one complication was seen in the entire series, a small subcutaneous abscess beneath the eye requiring incision and drainage. This abscess developed at the site of the erysipelas, in the region of an infected squamous cell carcinoma. There were no recurrences of erysipelas lesions.

Rantz and Keefer,⁹ in their report, stated that complications occurred most frequently in those patients

who did not receive the drug until late in the course of the illness. This has not been our experience. Treatment was begun with the history of the lesion existing from twelve hours to fourteen days before admission in our group of patients. Response of the individual lesion to sulfanilamide was universally prompt regardless of its duration.

As already noted, sulfanilamide was given to 102 of the 165 patients reported in this series. This drug is inexpensive but has the disadvantage of producing toxic symptoms, particularly in older persons. Nausea and methemoglobinemia were frequent. There were occasional occurrences of toxic psychoses with complete disorientation of the patient. Infrequent cutaneous rashes were seen.

Sulfamethylthiazole, although never put on the market and now prohibited from further clinical use, gave excellent results in 29 cases. It was found, in general, to be somewhat less toxic than sulfanilamide. No peripheral neuritis was seen in this small group of patients.

We have no evidence that sulfabamide has wide applicability as a therapeutic agent. In erysipelas, however, it seems to be as valuable as sulfanilamide or sulfamethylthiazole, and in our limited experience it was gratifyingly free from toxic effects. None of

TABLE 3—Duration of Fever After Therapy Was Begun

Number of Patients	Febrile Period After Beginning Chemotherapy	Percentage
84	24 hours	50.9
49	48 hours	29.7
12	72 hours	7.2
4	96 hours	2.4
16	Afebrile throughout	9.7
165		

the 34 patients had any apparent methemoglobinemia, and there were no gastrointestinal disturbances. Two morbilliform cutaneous rashes were seen but disappeared despite continuance of the drug. Mental confusion, so frequently seen in aged persons when given sulfanilamide, was not observed with this new drug.

SUMMARY AND CONCLUSIONS

1. One hundred and sixty-five consecutive erysipelas patients in the St. Louis Isolation Hospital were treated with sulfonamides, with a mortality rate of 3 per cent. Patients over 60 years of age, with chronic heart and kidney disease, furnished 4 of the 5 fatalities among this group.

2. In no instance was the lesion ever seen to spread after the first thirty-six hours on chemotherapy. A small subcutaneous abscess was the only complication. There were no recurrences.

3. In 84 patients an elevated admission temperature had returned to normal after twenty-four hours and remained normal. In 16 cases fever persisted over forty-eight hours but in no instance longer than four days.

4. Sulfanilamide was found to be fairly toxic, particularly for the aged patients in this series. The new drug sulfabamide, used experimentally for 34 patients, produced equally good results, without the usual toxic effects so common to the sulfonamide group of drugs.

5. The prompt response of erysipelas to the sulfonamides makes this the treatment of choice and renders other therapeutic measures obsolete.

INTERSTITIAL EMPHYSEMA IN DIABETES MELLITUS DUE TO COLON BACILLUS INFECTION

REPORT OF FOUR CASES

CARL L. GILLIES, M.D.

IOWA CITY

The development and spread of gas in the soft tissues is usually considered *prima facie* evidence of anaerobic gas bacillus infection.

It is not generally appreciated that colon bacilli either alone or in association with other aerobic bacteria can, in a patient with diabetes mellitus, produce interstitial gas and the severe constitutional symptoms characterizing gas gangrene.

Chiari¹ in 1893 reported the first case of the formation of gas due to colon bacillus infection in the tissues of a person with diabetes. After the death of his patient he was able to obtain pure cultures of colon bacillus from all organs, the blood and the soft tissues. Inoculation of animals with the organism failed to produce gas. Chiari therefore expressed the belief that the diabetes favorably conditioned the patient for the production of gas in the soft tissues by the colon bacillus.

Hitschmann and Lindenthal² in 1899 reported a similar case in which a clinical diagnosis of gas gangrene had been made. Bacteriologic studies, however, showed the absence of all anaerobes and the presence of the colon bacillus, *Streptococcus pyogenes* and a species of rods that could not be identified. Of these three, the colon bacillus was the only organism that produced gas on culture mediums. Hitschmann and Lindenthal concluded that the colon bacillus produces interstitial gas only in the presence of diabetes. Experimental work by them on depancreatized dogs was unsuccessful.

Warren³ has seen 2 diabetic patients with a clinical diagnosis of gas gangrene. Repeated studies for anaerobic and aerobic bacteria, together with inoculations in guinea pigs, failed to reveal any organisms other than colon bacilli and staphylococci. Warren has observed an additional diabetic patient whose kidney was outlined by gas in a roentgenogram, but apparently the causative organism was not cultured.

Since becoming aware of the possibility of the formation of gas in the soft tissues of diabetic patients with colon bacillus infection, I have seen 4 cases of this condition within two years. It would therefore appear that the condition must be much more common than the dearth of reported cases would indicate and that it is worth while again to call attention to this manifestation of disease.

From the Department of Radiology, State University of Iowa Hospitals.

Case 1 has been reported in detail and the report is to be published in the *American Journal of Roentgenology and Radium Therapy* under the title *Spontaneous Renal and Perirenal Emphysema: Report of a Case in a Diabetic from Escherichia Coli Infection*, by Carl L. Gillies, M.D., and Rubin Flocks, M.D.

REPORT OF CASES

CASE 1.—E. E., a woman aged 52, entered the hospital on May 20, 1939 because of obstruction of the lower part of the urinary tract.

The patient was known to have had diabetes for the past nine years. On admission the level of blood sugar was 433 mg. per hundred cubic centimeters. The diabetes was difficult to control, and in spite of the administration of 50, 30, 35 and 25 units of insulin daily the patient passed from 26 to 80 Gm. of dextrose in the urine when receiving a diet containing 250 Gm. of potential dextrose.

An indwelling catheter was left in the bladder to relieve the symptoms of obstruction while an attempt was made to get the diabetes under control. On May 25 a severe infection of the urinary tract developed. Cultures showed only the colon bacillus.

The patient continued on a downhill course. A roentgenogram of the urinary tract taken June 20 plainly showed a small amount of gas within the parenchyma of both kidneys. On June 21 another roentgenogram (fig. 1) showed extensive infiltration of gas within both kidneys and in the soft tissues around the kidneys and the adrenal glands.

In the evening of the same day the patient was taken to the operating room and the right kidney exposed. There were a great many blebs present, and bubbles of gas escaped as

Fig. 1.—Both kidneys and adrenal glands are outlined by gas which developed within the soft tissue.

the fatty capsule and the true capsule of the kidney were opened. No odor of gas could be detected. The patient went into shock and died shortly afterward.

Cultures of material obtained from the right perirenal tissues at the time of operation and cultures of blood taken shortly before death showed only the colon bacillus.

CASE 2.—A. S., a man aged 63, entered the hospital on April 19, 1940 with symptoms of obstruction from a carcinoma of the rectum. On April 22 a double-barreled colostomy was done. The patient had moderate diabetes, with a blood sugar level of 420 mg. per hundred cubic centimeters on admission. Because of the operation no food was given by mouth, but 300 Gm. of dextrose without insulin was given intravenously daily. The urinary excretion of dextrose during this period varied from 6 to 53 Gm. every twenty-four hours.

The postoperative course was uneventful until the seventh day, on which signs of a severe infection developed, with a temperature of 104 F. and rapid pulse and respiration. Crepitus was observed in both thighs, and a clinical diagnosis of probable gas bacillus infection was made. A roentgenogram of the right thigh made about four hours before death showed extensive interstitial gas (fig. 2).

At postmortem examination an adenocarcinoma of the rectum that had invaded through the rectal wall was observed. Metastases were present in the liver. There was acute cellulitis

of both thighs, with crepitation extending up over the buttocks. Postmortem cultures of the blood showed colon bacilli and alpha hemolytic streptococci. Cultures of material from the peritoneal cavity in the region of the pelvis showed colon

Fig. 2.—Gas is observed within the interstitial tissues of the medial surface of the thigh and on the outer surface below the greater trochanter.

bacilli. Cultures of material from the soft tissues of the right thigh were negative for gas bacilli of the *Clostridium* group but gave pure cultures of colon bacilli.

CASE 3.—D. McV., a man aged 62, was admitted on June 17, 1940. He appeared seriously ill. The left foot showed a gangrenous ulcer on both the plantar and the dorsal surface extending more than halfway to the ankle. There was swelling of the ankle, with definite crepitation anteriorly. Roentgenograms confirmed the presence of gas within the soft tissues (fig. 3).

A diagnosis of diabetic gangrene with severe infection and formation of gas was made. A supracondylar amputation at the thigh was done immediately.

Fig. 3.—Bubbles of gas are present in the soft tissues of the plantar aspect of the foot and anterior to the ankle joint.

Cultures made from necrotic muscle of the amputated leg and foot revealed *Staphylococcus aureus* and the colon bacillus. Cultures for anaerobic bacteria were negative.

The patient's diabetes was not studied until after operation. When the urine was first seen there were large amounts of

acetone and dextrose present. The diabetes was moderately severe, requiring for control 50 units of insulin with a diet containing 170 Gm. of potential dextrose.

The postoperative course was satisfactory, and the patient was discharged on July 14.

CASE 4.—G. W., a man aged 50, entered the hospital on Jan. 6, 1941 because of an infection of the right thigh. This had developed at the site of an injection of insulin three days before.

The patient was acutely ill. The upper part of the thigh was indurated and showed crepitus. The inguinal lymph glands were enlarged and tender. Roentgenograms showed bubbles of gas within a band of soft tissue 2.5 by 25 cm. lying below and parallel to the inguinal region (fig. 4).

The infected area was widely incised on January 6. A foul exudate and necrotic tissue were present. The odor of a colon bacillus infection was noted. Further incision was done on January 15, at which time the skin flaps were sutured back. The patient made a slow but satisfactory recovery.

Cultures of tissue obtained on January 6 showed alpha hemolytic streptococci and were negative for Welch bacilli.

Cultures of exudate taken on January 12 showed hemolytic staphylococci (*Staph. aureus*) and alpha hemolytic streptococci and were negative for Welch bacilli.

Because the organisms found did not explain either the presence of gas in the soft tissues or the odor of colon bacillus infection, further material for culture was obtained on Janu-

Fig. 4.—A narrow band of gas bubbles extends from the groin upward and outward to a point above the greater trochanter of the femur.

ary 21 and mediums favoring the growth of colon bacilli were used. At this time colon bacilli, hemolytic staphylococci (*Staph. aureus*) and anaerobic beta hemolytic streptococci were found.

This patient had known of his diabetes for eight years and before entrance had been requiring 36 units of protamine zinc insulin daily with a diet containing about 215 Gm. of potential dextrose.

When first seen in this hospital and at the height of the infection he received 36 units of protamine zinc insulin plus 45 units of regular insulin daily. On a diet of 390 Gm. of potential dextrose he excreted 42 to 52 Gm. of dextrose.

The diabetes has improved along with the infection. It is now controlled by 35 units of protamine zinc insulin plus 10 units of regular insulin daily, with the patient on a diet containing 290 Gm. of potential dextrose.

COMMENT

The ability of the colon bacillus to produce gas from culture mediums containing carbohydrates is well known. While this organism alone can probably on

occasion produce interstitial gas in a nondiabetic patient, it seems logical to assume that the presence of an increased dextrose content of body fluids and tissues offers a situation more favorable for the production of gas.

In support of this belief are the reported cases of the formation of gas in the urinary tract of diabetic patients with colon bacillus infection. It appears to be well established that at least one of the causes of primary pneumaturia is the decomposition of sugar-containing urine in the bladder by the colon bacillus.⁴

Olsson⁵ reported a case in which gas was roentgenographically demonstrated in the renal pelvis of a diabetic woman who had pyelonephritis caused by the colon bacillus.

Sanes and Doroshow⁶ reported 2 cases of cystitis emphysematosa with colon bacillus infection. One patient was a diabetic woman and the other an infant aged 3 months who had been receiving dextrose intravenously. These writers also noted association of an elevated sugar content of the blood with colon bacillus infection.

Marquardt⁷ has recently reported another case of cystitis emphysematosa, in a diabetic woman aged 56 from whose urine were cultured the colon bacillus and *Streptococcus lactis*.

A most unusual case of formation of gas was reported by Reis.⁸ Gas bubbles were observed in the anterior chamber of the eye of a diabetic woman with ophthalmitis thought to be due to the colon bacillus.

In diabetic gangrene not only is there an increased amount of sugar in the tissues but the impaired circulation delays absorption of any gas that may form.

In cooperation with Dr. James Greene two attempts were made to produce interstitial gas experimentally by injecting strains of the colon bacillus in the leg of a depancreatized dog whose diabetes was only partially controlled by insulin. We were unable to detect gas either clinically or roentgenographically, and the dog recovered completely from both infections. Because of the known resistance of dogs to colon bacillus infection, we do not consider the experiment comparable to similar conditions in man.

The histories of patients with true gas gangrene treated in this hospital have recently been reviewed by Bartels.⁹ During the past ten years there have been 45 patients for whom the diagnosis of gas gangrene has been confirmed by the bacteriologic identification of anaerobic gas-producing bacteria. Of this group 9 were known to have diabetes. All had diabetic gangrene, but in only 1 was gas detected before amputation. In 8 the signs and symptoms of gas gangrene developed in the stump after amputation for diabetic gangrene.

CONCLUSION

With any diabetic patient showing signs of infection and the presence of interstitial gas, the possibility of colon bacillus infection should be considered first in the differential diagnosis from true gas gangrene produced by anaerobic organisms.

HALITOSIS

BURRILL B. CROHN, M.D.

AND

RUDOLPH DROSD, M.D.

NEW YORK

Interest in halitosis, or abnormally foul breath, has to a large extent been preempted by the oral surgeon and the rhinologist; from the references in the general literature one would surmise that it is a rare disease instead of a common condition, so little interest in the subject having been shown in the past. Every writer on the topic has emphasized the mouth, the teeth and the pharynx as sources of bad odors on the breath, attributing the fetor to decaying teeth, pyorrheal abscesses and necrotic pathologic processes in the pharynx, such as breaking-down tumors and gummas. Obviously, with the present national campaign of education and the much improved care of the teeth and the gums in children and in adults, the mouth has receded in importance as a source of bad breath; such conditions as necrotic growths are unusual and of academic interest only and play a small part. The teeth, the gums and the pharynx account for true fetor ex ore but do not explain the internal malady known familiarly as halitosis.

Our attention was attracted to this subject by the controversy which arose between two sets of observers who reported the effects of the oral administration of garlic on the exhalations of normal persons and of patients. In 1935 Haggard and Greenberg¹ reported on the feeding of raw garlic and stated that the odor of garlic on the breath resulted only from particles of the substance retained in the crevices of the teeth. When the garlic was ingested by capsule, no odor on the breath resulted. They claimed to have been able to eliminate the odor from the mouth by the use of chlorinated washes and preparations. A year or so later, Blankenhorn and Richards² contradicted the claims of Haggard and Greenberg. By inserting garlic via a gastrostomy tube into the stomach of a patient with complete stenosis of the esophagus, they were able to recover the odor of the garlic on the breath. With another patient, on whom tracheotomy had been performed for laryngeal carcinoma, the odor of garlic was recovered in the exhalations from the tracheotomy tube. Obviously, garlic had been absorbed by the gastrointestinal tract and its odor emitted via the lungs and the breath, even though all connection between the stomach and the mouth had been surgically eliminated.

Opposing views as to the source of a garlic odor on the breath were thus represented: (1) that the mouth and teeth are the offenders and (2) that the breath is the excretory channel of absorbable malodorous materials.

OBSERVATIONS ON PATIENT W.

An unusual combination of clinical conditions in a single patient presented an opportunity for the study of odors on the breath. This patient (W.), seriously ill with ulcerative colitis, had undergone colostomy for obstruction low in the intestine (in the middle part of the transverse colon) and ileostomy as a life-saving

measure. In the latter operation the terminal portion of the ileum had been transected and both stomas anchored in the abdominal wound. In addition, the patient having a toxic psychosis, an indwelling gastric Levin tube had been inserted and was maintained in place for feeding.

The first observation of interest relates to the persistence of a strong odor of paraldehyde on the breath of the patient forty-eight hours after the administration of the drug by gastric catheter. The discharge from the site of the ileostomy was free of odor, the colon was surgically isolated and yet the odor on the breath was strong. It was a simple matter to wash out the stomach and prove that no trace of the drug remained in the gastric secretions; nevertheless for two days the odor of paraldehyde emanating from the mouth permeated the room.

The patient provided an ideal combination of conditions for the observation of other odors, particularly that of garlic, on the breath, since one could study mouth, stomach, ileum and colon as almost independent and isolated units.

The following set of simple experiments afforded a factual basis for thought and for application when directed toward the clinical explanation of true halitosis.

EXPERIMENT 1.—On April 17, 1940 at 4 p. m. the patient was given through a gastric catheter 1 cc. of concentrated extract of raw garlic (a water-alcohol trituration). There was no odor on the breath until 7:20 p. m., when the odor of garlic first became evident on the exhaled breath and in the ileostomy drainage. Evidently the odor was not present on the breath when the garlic extract was in the stomach alone but made its appearance only after the extract had reached the small intestine.

This experiment was repeated, and it could easily be demonstrated by gastric aspirations that, though the gastric content was redolent of garlic for two hours after its insertion through the tube, no odor could be detected in the mouth until the vegetable matter had reached the small intestine and presumably been absorbed.

EXPERIMENT 2.—On October 8 the patient had 3 cc. of garlic extract injected into the stomach through a Levin tube at 4:40 p. m. At 6 p. m. there was no odor on the breath but the gastric aspirate was definitely odorous of garlic. At 6:40 and 7:30 p. m. the breath was strong in garlic odor, as was the ileostomy drainage.

On October 9 at 8 a. m. the odor had persisted on the breath and in the ileostomy drainage after sixteen hours; the gastric aspirate had no odor after sixteen hours. At 6 p. m. the odor on the breath was still fairly strong, but there had been none in the ileostomy drainage or in the stool since 8 a. m. after twenty-six hours.

On October 10 at 9 a. m. the odor of garlic was still present on the breath (after forty hours); it persisted until 2:30 p. m. (forty-five and one-half hours altogether). At 5 p. m. (after forty-eight hours) there was no odor on the breath.

The garlic odor on the breath was not present in the first hours, even though garlic could be demonstrated by aspiration to be residual in the stomach, but was present long after the gastric aspirate was free of garlic. The odor persisted in the mouth more than twenty-four hours after the stomach, ileum and colon were shown to be free of a persistent residue of garlic.

EXPERIMENT 3.—On October 11 the patient had 5 cc. of garlic extract injected into the distal loop of the ileum at 9:45 a. m. By 10:45 a. m. a faint odor had appeared on the breath; it was still present though faint at 5 p. m.

Apparently absorption from the distal part of the ileum and the colon does take place, and the substance is excretable on the breath. (The constant diarrheal

movements of the patient probably interfered with full absorption.) The stomach, the upper part of the ileum and the jejunum play absolutely no part.

When experiment 3 was repeated, with the garlic inserted into the proximal loop of the ileum, prompt absorption was demonstrated by the appearance of the odor on the breath within three hours.

EXPERIMENT 4.—In order to ascertain the role of the teeth and the mouth as isolated organs in maintaining a characteristic odor, the anterior and posterior surfaces of the patient's teeth and the interstices were painted with a strong garlic extract by means of a camel's hair brush, no saliva being swallowed. For one hour only there was a strong garlic odor on the breath; soon thereafter no odor was detectable.

To check up on the foregoing surprising observation, a normal person was asked to chew some strongly garlickized salami, swallowing none of it and expelling all his saliva. Large particles of salami were driven into the interdental spaces. The immediate odor on the breath was powerful, but within an hour only a faint odor remained, and within two hours no odor of garlic was detectable.

EXPERIMENT 5.—Whisky, instead of garlic, was employed in order to evaluate the role of the mouth alone in halitosis. Normal persons were asked to rinse the mouth and teeth with strong rye whisky, swallowing being suspended during the operation. The whisky odor was retained on the breath only twenty to thirty minutes.

A normal person introduced into the fasting stomach a Levin tube, then rinsed the mouth and teeth with good rye whisky and swallowed an abundant amount. Immediately the ingested whisky was siphoned out of the stomach and the gastric chamber washed with warm water. Within twenty minutes even the slightest whisky odor had disappeared from the breath.

These experiments were repeated on the psychotic patient W. When whisky was injected through the Levin tube, care being taken to avoid all contamination of the mouth, no odor was immediately apparent on the breath, though by repeated aspirations of the gastric contents the whisky was shown definitely to have been retained in the stomach. At no time did a whisky breath become evident; presumably the quantity necessary to produce an alcoholic breath far exceeds the therapeutic dose, and apparently the whisky must first be absorbed.

GROUP OBSERVATIONS

A more extensive study of garlic and other odorous substances was undertaken with large numbers of hospital patients in order to trace the path of absorption, excretion and exhalation of such substances. Patients with a jejunostomy, ileostomy or colostomy opening, a short-circuiting anastomosis, a gastrojejunocolic fistula or pyloric stenosis were utilized, as well as many subjects who had undergone resection of a segment of the small intestine or partial or complete colectomy.

Raw chopped garlic was enclosed in double gelatin capsules for oral administration, and the same capsules were used for insertion into various bodily apertures, natural and artificial. The dose of garlic ranged from 0.5 to 1 Gm.; however it was administered, a latent period of one-half to one or two hours ensued, during which no odor on the breath was demonstrable; thereafter a strong odor occurred, which lasted for four to twenty-six hours and then tapered off to a musty faintness. Children were found most susceptible to small doses; women were much more susceptible than men. The garlic was absorbed from all parts of the intestinal tract, large or small, regardless of the extent of the resection which had been performed. No garlic seemed to be absorbed from the stomach in cases of complete pyloric stenosis. If belching or vomiting took place

while the stomach contained garlic, the odor was immediately apparent on the breath. As long as the cardia acted as an effectual valve, no odor could be observed.

Once the garlic was in the intestine, cathartics and enemas were ineffectual in ridding the intestine and the breath of garlic odor. One or two doses of a saline cathartic were eventually effectual if the amount administered was sufficient and the effect obtained soon enough after ingestion.

When garlic and indigo carmine were inserted into a jejunostomy opening, the odor appeared on the breath in one-half hour and persisted for nineteen hours; during that whole period the indwelling gastric catheter proved that none of the material had been regurgitated into the stomach. Evidently the mechanism of reverse peristalsis plays little part in the production of garlic halitosis, a fact which has much negative significance in the interpretation of the meaning of true halitosis.

ROLE OF THE LIVER AND BILE IN THE TRANSMISSION OF GARLIC ODORS

It was at this point apparent that garlic halitosis depended on absorption of the material from the intestine and was independent of an oral or a gastric mechanism. But it was also noted, by observations made on patients with various intestinal stomas, that long after the garlic odor had disappeared from ileac or colonic washings and drainage fluids the oral odor persisted. One of our earliest observations was that the ileostomy drainage ceased to smell of garlic after seven hours but that the breath gave off the odor for fully forty hours longer.

Where in the body was the garlic being stored? Naturally our first thought was the liver, one of whose functions is the storage and detoxification of foreign materials. We were able to utilize in our experiments 3 patients with carcinoma of the pancreas and complete obstruction of the bile passages in whom biliary drainage had been surgically established. When 0.5 Gm. of garlic (in a capsule) was administered by mouth the typical garlic odor was detectable in the bile within one or more hours. The same held true when the garlic was administered by rectum. The odor in the bile persisted for fifteen hours; on the breath it lasted twenty-five. In another experiment a saline cathartic was given six hours after the ingestion of garlic; the laxative failed to have effect, since the odor persisted in the bile for twenty-two hours and on the breath for twenty-four. Odor in the bile and odor on the breath appeared almost simultaneously, but that on the breath always persisted for one to two hours after the bile had ceased to be malodorous. Once the bile drainage became redolent of garlic, it was not possible to drive out the odor by the use of saline laxatives or to shorten its expected duration. We should like to have tried the effects of mild mercurous chloride or cholagogues on the duration of the garlic odor in the bile, since it seems logical that a true cholagogue would materially curtail the duration of such an odor. There has not been sufficient opportunity or time for all the experiments which suggest themselves. However, this much is true: After the liver cleaned itself of the garlic odor, the breath followed suit within a few (usually only two) hours.

OBSERVATIONS WITH VOLATILE SUBSTANCES

Many of the experiments in which garlic had been employed were repeated with oil of peppermint and oil of wintergreen in order to ascertain some simple facts. We wished to know whether other volatile odorous substances travel the same route from intestine to liver

to lungs and to breath and whether such pleasant odorous matters are exhaled on the breath. In general, the volatile oils of peppermint and wintergreen acted exactly as had garlic. Children and women excrete peppermint on the breath when it is given in moderate doses; men excrete it with less facility and only when it is given in much larger amounts. Oil of wintergreen is much less potent than peppermint, large doses being necessary to produce the odor on the breath. When peppermint and garlic were given simultaneously it was not possible completely to mask the garlic odor even by large doses of peppermint oil. The odor of peppermint could be recovered from the bile drainage of patients with cholecystectomy openings when the oil had been administered either orally or rectally. With the oral dose, the odor on the breath lasted one to six hours; with the rectal dose, the odor persisted in the bile only one to two hours.

During these experiments we observed a patient suffering with diffuse eczema of the trunk and the extremities, to which liberal applications of a mentholated ointment had been applied to allay the pruritus. The breath of this patient smelled strongly of menthol. This fact should not seem unusual, since it has been known that oil of garlic applied to the soles of the feet of a child can give rise to garlic breath.³ We were easily able to reproduce this simple phenomenon of cutaneous absorption and exhalation on the breath with pure oil of garlic applied to the skin of a child.

Skatole and indole were investigated because they had long been considered important intestinal factors underlying true halitosis. Indole, in doses of 25 to 250 mg., was administered by mouth (in capsule form) to patients of various ages and of both sexes. With the larger doses, several persons had toxic symptoms of nausea and lassitude; the odor of indole usually appeared on the breath one hour after ingestion, and it endured for one to thirteen hours. It could be easily overcome by administering oil of peppermint.

The ingestion of skatole in capsule form creates a peculiar musty odor not unlike that of true halitosis but weaker and of shorter duration than the odor caused by indole or the other volatile substances used in experiments.

COMMENT AND CLINICAL APPLICATION

What relation do the interesting pharmacologic observations mentioned bear to the elucidation of the problem of true halitosis?

Unless pathologic oral or nasopharyngeal conditions exist, the mouth, the teeth and the pharynx play little or no part in the production of essential halitosis. Nor, for that matter, does the stomach play a part, for it can easily be shown that with a perfectly functioning cardiac sphincter, malodorous substances introduced into the stomach do not, by their mere presence, taint the breath. One can verify this point by smelling the breath of patients with pyloric stenosis, whose gastric content is always rancid and malodorous. Providing neither vomiting nor belching has recently occurred, the breath of such patients is not redolent of the characteristic vile-smelling gastric residue.

A patient with gastrojejuno-colic fistula was observed; the fistulous tract was large and broad and had established itself between the transverse colon and the stomach. When the patient belched, a vile fecal odor was apparent on the breath; otherwise halitosis was absent.

3. Silverstine, C. T.: Garlic Breath Odor, *Ohio State M. J.* 32: 1232 (Dec.) 1936. Peechey, John: *The Compleat Herbal of Plants*, ed. 2, London, 1707.

Obviously the intestines, large and small, are the critical points, for the mucosa allows the absorption of noxious materials, their transport to the liver and their further migration, apparently by way of the circulation, to the lungs and thence to the breath. That this is the route traversed by garlic can be easily demonstrated. We have traced the garlic as far as the liver and the biliary excreta. That garlic is and can be carried in the blood stream has been shown by Goodman and Bearg,⁴ who demonstrated on the breath of newborn infants the odor of garlic which had been ingested by the mother before delivery. Since the only method of transference would be for substances to pass from the maternal circulation through the placenta to the fetal circulation, it must be assumed that the blood can carry garlic in solution. The lungs function as an organ of excretion, withdrawing volatile materials from the circulating medium and exhaling them on the breath. Similarly, when paraldehyde is injected intravenously the odor appears rapidly on the breath and persists for forty-eight hours.

Let the hypothesis be made that essential halitosis is the excretion on the breath of malodorous fats, fatty acids or volatile substances resultant from some fault in the digestion or metabolism of fat. The noxious volatile matter is absorbed from the intestinal tract (probably from the lower part of the ileum), is carried to the liver (where insufficient or ineffectual neutralization or detoxification ensues), is partly excreted in the bile but in the main is picked up by the circulating blood, which in traversing the alveoli of the lungs parts with the substance, which is exhaled on the breath. What clinical facts can be brought forward to substantiate such a hypothesis? It has been noted that the Chinese strenuously object to the body odor of white persons and attribute that odor to the milk and butter which Caucasians so freely ingest (Snapper).⁵ Caucasians are said by the Chinese to smell of "cow." We have observed that patients with ulcer given a Sipsey diet or, particularly, treated by the continuous milk drip method frequently have true halitosis. If such patients are given a diet of cereal, eggs and lean meat—a diet of low fat content—the typical odor disappears. If a high fat diet containing butter and milk is reinstated, the halitotic odor will readily recur.

Patients suffering from true halitosis are similarly amenable to the therapeutic test of a low fat diet. If a reducing diet, low in fats (40 to 60 Gm. a day), is administered, a prompt disappearance of the halitotic odor occurs.

Our clinical observations are as yet too few and too recent to allow us to make our hypothesis a categorical statement, but the therapeutic suggestiveness of the procedure seems promising.

A direct attack on the intestine and the liver should also merit attention, for these are the sources of the disagreeable odor. A single moderate dose of a saline laxative does not clear up halitosis. If the laxative is given daily in larger doses, the oral odor is much ameliorated.

Colonic irrigations are less effectual in reducing the oral fetor, a fact which makes us believe that the small rather than the large intestine is the sink of iniquity. Constipation in itself seems to play little part in the production of halitosis.

What part the liver plays remains at this point conjectural. We were unable to drive out the odor of garlic

from the bile by the use of saline laxatives or cathartics, but, again, insufficient time and experiments preclude final deductions. Perhaps a true choleric would serve such a useful purpose successfully.

It would be alluring to think of covering a true halitotic odor by the administration of oil of peppermint or oil of wintergreen. If the oil were ingested in sufficient amount, the exhaled odor might within two to three hours overcloud the halitotic odor and replace it with a less noxious if not an agreeable one.

Mouth washes containing pleasantly odorous materials serve to hide or mask true halitosis as a temporary measure but fail completely to meet the problem, since the source of the fetor is in the intestine and the metabolism. A true attack on the problem must be directed to the fatty or volatile constituents of the diet and their elimination via the liver, the intestinal tract and the lungs.

This report is intended as a preliminary rather than as a finished study. The amplification of our hypothesis and its tentative implications in the study of large numbers of patients with true, or essential, halitosis would require considerable time, patience and accurate observation. Methods of precision and titrimetric estimations of odors have in our hands proved less satisfactory than the direct use of the nose. The clinical application of our hypothesis to the study and elimination of essential halitosis should readily prove the theory of the intestinal origin of halitosis and the hepatic storage of halitotic agents, or the theory should be corrected and revised by additional facts and observations.

THE ORAL MANIFESTATIONS OF VITAMIN DEFICIENCIES

LOUIS A. ROSENBLUM, M.D.

AND

NORMAN JOLLIFFE, M.D.

NEW YORK

As the main system for the ingestion and absorption of foodstuffs, the gastrointestinal tract occupies a prominent position in the causation of vitamin deficiencies. Thus it has been pointed out that "any pathologic condition which interferes with normal food intake, normal digestion, normal absorption of the products of digestion, and normal utilization of these products by the liver, may produce secondary or conditioned avitaminosis."¹ In addition, the gastrointestinal tract is one of the first systems to present objective clinical signs when deficiencies of certain vitamins occur.

An examination of the diets usually prescribed for patients with peptic ulcer, colitis and disease of the gallbladder shows that they often consist mainly of refined carbohydrate and are apt to be deficient in one or more of the vitamins. Patients with idiosyncrasies regarding food expressed in the diet they select will more often than not favor refined foods low in vitamins. On the

5. Snapper, I.: Personal communication to the authors.

other hand, even when the prescribed or self-selected diet is adequate in vitamin content, medication may destroy the vitamins contained in the ingested food or interfere with their absorption. In the presence of alkalis vitamin C, thiamine, riboflavin and perhaps other vitamins are inactivated. The use of active colloidal adsorbents, such as magnesium trisilicate, aluminum hydroxide and mixtures of these two, in the treatment of peptic ulcer raises the problem as to the amount of vitamins, particularly the water-soluble vitamins B and C, that is adsorbed onto these compounds and excreted without being utilized. This is more than speculation, because such adsorbents are extensively utilized in the isolation and purification of many biochemical substances, including the vitamin B components. Anderson² has demonstrated that the ingestion of liquid petrolatum along with vitamins A and D will cause solution of the vitamins in the oil, with their resultant excretion and nonutilization.

From the surgical aspect, the liberal use of fluids parenterally in the form of solutions of dextrose has contributed a great deal to the production of sub-*vitaminosis* B in patients who have undergone operative procedures on the gastrointestinal tract. The same danger prevails in other states in which parenteral feeding is resorted to for any reason. The excessive amounts of vitamin-free carbohydrate quickly deplete the body's meager stores of the vitamin B complex, and deficiency symptoms appear after several days of parenteral feeding with dextrose. So-called water intoxication, attributed to the excessive administration of fluids parenterally, may often be actually the syndrome of wet beriberi and may respond rapidly to the administration of thiamine hydrochloride in adequate amounts. Production of nicotinic acid deficiency and perhaps deficiency of other components of the vitamin B complex may also follow the prolonged parenteral use of carbohydrate. Hence it is a wise prophylactic measure to administer thiamine hydrochloride, riboflavin and nicotinic acid to all patients receiving fluids parenterally, either by giving the substances separately or by including them in the dextrose solutions.

Among the principal causes of deprivation of vitamins despite an adequate intake are the diarrheal states, especially when of long duration, as in cases of colitis, sprue and intestinal tuberculosis. Dann and Cowgill³ have demonstrated that the experimental production of diarrhea in dogs considerably increases their requirement of thiamine. The diarrheal factors and the manner in which they produce vitamin deficiencies were discussed in a recent paper by Bean and Spies.⁴ They emphasized besides the mechanically increased loss due to rapid passage of the intestinal contents through the body, such other factors as failure of the normal enzymic breakdown of foods because of the decrease or absence of the digestive secretions and the prevention of absorption caused by anatomic changes associated with chronic intestinal disease and diarrhea, such as scarring, induration or inflammation of the intestinal wall. They suggested, in addition, that the phosphorylation of foodstuffs, which is necessary for the activation of vitamins and which takes place in the

intestine, is probably interfered with in diarrhea. Lastly, they pointed out that fever, which coincidentally increases the metabolism and the requirement of vitamins, and symptoms such as nausea and pain reduce the intake of food, with consequent limitation of the intake of vitamins.

From the foregoing remarks one may realize the importance of the gastrointestinal system in the body's vitamin economy, not only as the main route for the introduction of vitamins but also as the means of elution from foodstuffs, absorption and transformation into active forms. The possible development of deficiency states in patients with gastrointestinal disorders must be carefully evaluated, since the onset of a deficiency syndrome usually provokes a vicious cycle; in vitamin B deficiency the absorbing and utilizing powers of the alimentary tract are interfered with, and this progressively exacerbates the symptoms of deficiency. Administration of the entire vitamin B complex and, in addition, any of the synthetic factors, as indicated, is of prophylactic value in all cases of disease of the gastrointestinal tract. In the absence of simple and rapid laboratory tests for vitamin deficiency states, the importance of recognizing the oral manifestations of vitamin deficiency is obvious.

Lesions of the lips, gums, tongue and buccal mucous membranes are characteristic of deficiency of vitamin C and of several members of the vitamin B complex. Response to specific therapy is mirrored rapidly by changes in these lesions. We believe therefore that these early and characteristic phenomena may be used not only in diagnosis but for the evaluation of therapy.

Characteristic oral lesions are commonly observed in deficiency of vitamin C, or scurvy. These, however, are rarely isolated and are usually colored by the presence of other deficiencies. As the function of vitamin C is concerned with the formation and regulation of the intercellular matrix, the gingival lesions are due to a vascular diathesis which produces swollen and boggy gums that bleed easily and progress to actual ulceration. Chewing is difficult, and involvement of the alveolar bones causes the teeth to loosen and fall out. The teeth themselves may be affected by the scorbutic process, the dentin and enamel becoming porous and defective, with resulting rapid and early decay. Hemorrhage into the buccal mucosa may result from the damage to the vascular epithelium.

Investigations thus far have disclosed no oral lesions characteristic of thiamine deficiency. Characteristic stomatitis and glossitis are diagnostic of nicotinic acid deficiency.⁵ These appear early in the course of the disease as swelling and redness of the tip and the lateral margins of the tongue. With the progression of the disease, the reddening becomes more intense until these parts assume a fiery scarlet hue. At the same time ulcerations appear along the sides, the tip and the under surface of the tongue and on the buccal mucosa, particularly opposite the molar teeth. These ulcerations are frequently covered with a thick grayish exudate or membrane in which *Vincent's organisms* can be found. The response to adequate nicotinic acid therapy is often dramatic. Blanching of the fiery redness usually occurs within twenty-four hours, and healing of the ulcerations may be noted in forty-eight to seventy-two hours.

Gastrointestinal, mental and cutaneous changes which may be present may not manifest equally dramatic response to treatment.

The first distinct clinical picture in man attributed to deficiency of riboflavin was demonstrated experimentally by Sebrell and Butler,⁶ who, by maintaining 18 women with the diet of Goldberger and Tanner, experimentally produced oral pallor followed by maceration and superficial transverse fissuring in the angles of the mouth. These lesions resembled those described as *perlèche*. At the same time a superficial denudation of the mucosa caused the lips to become abnormally red along the line of closure. "In addition to the cheilosis there was also seen a fine, scaly, slightly greasy desquamation on a mildly erythematous base in the nasolabial folds, on the alae nasi, in the vestibule of the nose and on the ears." Under the conditions of the experiment these lesions were alleviated by the administration of synthetic riboflavin but not by nicotinic acid. Since then this deficiency has been found prevalent as a spontaneous condition.⁷ Kruse, Sydenstricker, Sebrell and Cleckley⁸ have reported, in addition, a keratitis associated with these signs of riboflavin deficiency in 10 subjects.

We⁹ have reported on 15 subjects having lesions due, we believe, to ariboflavinosis. In addition to the riboflavin deficiency, 13 had nicotinic acid deficiency, 7 had vitamin B₁ deficiency and 3 had vitamin C deficiency, all clinically manifest. Only 1 patient showed no clinical evidence of another vitamin deficiency. Since then, however, we have observed innumerable subjects, including university students, nurses, dietitians and persons with high incomes, who presented a cheilosis that responded to riboflavin but who showed no clinical evidence of another deficiency disease. It is our belief that ariboflavinosis is the most common isolated deficiency that is objectively manifest.

The facial lesions seen in our cases of riboflavin deficiency consisted of filiform, seborrheic excrescences, in length up to 1 mm. apparently derived from the sebaceous glands and closely to sparsely scattered over the skin of the face. Their characteristic location was in the nasolabial folds, but they occurred frequently on the alae nasi, occasionally on the bridge of the nose and sometimes on the forehead above the eyebrows. The skin on which the excrescences were located was the seat of a fine, scaly, greasy desquamation. On casual inspection these filiform lesions resembled urea frost, but they could not be brushed off by rubbing with the fingers. In addition, most of the patients showed fissures and maceration at the angles of the mouth and a degenerative crustlike formation on the epithelium of the lips, most evident on the lower. The fissures occurred in both angles of the mouth and extended laterally 1 to 3 mm. onto the mucous membrane of the mouth and 1 to 10 mm. onto the skin. They were usually shallow but were sometimes 0.5 mm. deep, and their bases as a rule showed little or no increased red-

ness. In an area extending for 5 to 20 mm. from the angle of the mouth onto both lips, the mucous membrane was macerated, wrinkled and pearl gray. The lips, particularly the lower one, frequently showed a decided increase in the vertical fissuring, often without a break in the mucous membrane. Occasionally the vestibule of the nose was involved, with lesions similar to those on the lips.

The polymorphous nature of the lesions of the tongue and mouth found in patients with frank nicotinic acid and riboflavin deficiency is illustrated by the experience of having the affected areas, particularly the tongue, return to a normal texture and color only after the entire vitamin B complex, or a good diet containing its components, has been administered. Among the patients who still presented stomatitis and glossitis after treatment with nicotinic acid and riboflavin were a number in whom the tongue was smooth, slightly edematous and of a peculiar purplish or magenta hue. Often these patients complained of pain in the tongue. The tongue would return to normal after a sufficient amount of the whole vitamin B complex had been given. With the isolation and synthesis of vitamin B₆, or pyridoxine, it became possible to differentiate a lesion of the tongue that is probably due to a deficiency of this vitamin. The following case history illustrates this type of lesion and the manner in which it originates.

REPORT OF A CASE

D. R., a white woman aged 31, was admitted to our service in March 1940 because of emotional disturbances, with irrationality. There was a history of headaches, fatigue and weakness for two weeks and prolonged heavy drinking. The patient was confused and disoriented. There was bilateral nystagmus. The tongue and buccal mucous membranes were normal. There was no nasolabial dermatitis or cheilosis. The skin and the conjunctivas were moderately icteric. Palpation of the abdomen disclosed that the edge of the liver was firm at the level of the umbilicus, with prominent lateral abdominal veins but no evidences of fluid. The heart and lungs were without significant abnormalities. Treatment with nicotinic acid, ascorbic acid and vitamin A was instituted, while the patient was maintained with a basal diet.

The mental condition slowly improved, but on the third day the patient complained of soreness of the tongue. On examination the tongue was found to be somewhat smooth, most obviously about the edges, and purple-red, or magenta. The lower lip also was of this color, though there was no cheilosis. Thiamine hydrochloride was added to the therapeutic agents, the daily dose of nicotinic acid was increased to 1,000 mg. given orally in divided doses and 200 mg. of sodium nicotinate was given intravenously. This caused no change for the better in the tongue and lips; if anything the magenta coloring of the tongue was intensified, and the patient claimed that her tongue was becoming increasingly painful. On and after the eighth day of the foregoing regimen she was given, in addition, 100 mg. of pyridoxine hydrochloride (vitamin B₆) daily by intravenous injection. By the second day of treatment the soreness of the tongue had almost disappeared and the color had become distinctly lighter. On the fourth day the tongue was almost normal in color, with evidence of new papillae about the center area, which was still somewhat redder than normal. The following day the color had blanched further, and there was definite beginning regeneration of papillae. The lips also at this time had returned to an almost normal color.

The progressive production of characteristic glossitis in a patient maintained with a diet low in the vitamin B complex and supplemented by nicotinic acid, thiamine,

ascorbic acid and vitamin A and the rapid improvement and return to normal of the tongue when vitamin B₆ was administered constitute, we believe, experimental evidence of a vitamin B₆ (pyridoxine) deficiency.

We have observed, in addition, a stomatitis characterized by the persistence of redness of the mucosa and the presence of many small plaques, looking like milk curds, which could not, however, be washed or rubbed off the mucous membrane. The exact nature of the deficiency causing the stomatitis is not known. We have found this condition in pellagrins as a residuum after the stomatitis due to nicotinic acid deficiency had been healed. It does not respond to treatment with vitamin B₆, riboflavin or nicotinic acid, singly or in combination. Restoration of the mouth to normal was accomplished only after intensive therapy with the vitamin B complex. The factor or factors responsible are present in the vitamin B complex and may be any of the less well known fractions which have not as yet been isolated or synthesized and consequently have not been applied in human nutritional studies.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CROHN AND DROSD AND
DRS. ROSENBLUM AND JOLLIFFE

DR. THOMAS T. MACKIE, New York: Drs. Rosenblum and Jolliffe brought out a fact which needs constant emphasis: that many of the diets which we use in the clinical management are deficient from the point of view of nutrition. I should like to interject a note of caution about the too rigid interpretation of a particular sign and its association with deficiency of a particular crystalline product. I have seen instances presenting the physical signs said to be characteristic of ariboflavinosis that have not responded to heavy dosage of riboflavin until that was supplemented by large doses of brewers' yeast; furthermore, the nasolabial lesions which are described as resulting from ariboflavinosis in the hands of other observers have been described as clearing promptly, within a matter of four or five days, on the administration of nicotinic acid as well as of riboflavin. There is a possibility that the function of these specific factors is interrelated chemically and that the exhibition of one particular substance may lead to the clearing of a particular physical sign, not as a result of the specific action, but as the result of some improvement in general intracellular metabolism. The therapy that I employ whenever I deal with a proved or suspected avitaminosis must recognize that the most important agent is a properly balanced diet and that at the present time the held of usefulness of crystalline products is limited to the meeting of specific indications. One cannot use the shotgun preparations as a substitute for a proper dietary.

DR. W. H. SHEALY, Sharpsburg, Md.: I should like to ask about the treatment of pure Vincent's infection.

DR. LOUIS A. ROSENBLUM, New York: In the treatment of Vincent's angina with nicotinic acid it is important to differentiate between the presence of fusiform bacilli and spirochetes associated with the characteristic nicotinic acid deficiency stomatitis and the true or so-called dental Vincent's angina, which has a typical pseudomembrane and is without the fiery red appearance of the mucous membranes that is so characteristic of nicotinic acid deficiency. Probably the impaired tissue oxidations and other metabolic disturbances that occur in the presence of a deficiency of nicotinic acid provide the approach to the anaerobic environment apparently necessary for the proliferation of the Vincent's organisms; with return of the tissues to a normal metabolic status by the administration of nicotinic acid the organisms disappear and Vincent's angina is cured. But true Vincent's angina not associated with a nicotinic acid deficiency stomatitis does not usually respond to treatment with nicotinic acid.

Clinical Notes, Suggestions and New Instruments

INTERSEXUALITY PROVED BY OPERATION AND MICROSCOPIC EXAMINATION

ABNER I. WEISMAN, M.D., AND ALFRED SCHWARZ, M.D., NEW YORK

It is becoming more widely accepted, as science progresses, that there are few persons who are either wholly male or wholly female but rather that there is a little of the female in all men and a little of the male in all women. The ratio may sometimes be unduly exaggerated and far from the usual normal proportions, which may make it difficult at times to determine whether the individual is basically a male or a female. For this kind of person the term "intersex" has been coined. The case reported here presents one of these problems of intersexuality.

It is not within the province of this report to enter into the theories of formation, suggested mechanisms, hypothetical

after spermatozoal impregnation of the ovum the union and fusion of definite types of chromosomes at once determine the genetic sex of the future individual. (For example, when a spermatozoon containing an x-chromosome fuses with an x-chromosome of the ovum, a potential female offspring may be

Fig. 3.—Our conception of the patient's pelvic anatomy. This composite drawing was made from a number of photographs none of which singly showed the entire operative field.

assured. Similarly, when a sperm containing a y-chromosome fuses with an x-chromosome of the ovum an individual bearing the characteristics of the male is to be expected.) It should be borne in mind that each fused cell or zygote is potentially bisexual, even though under normal conditions the characteristics of one sex are dominant while those of the other are submerger.

factors with endocrine rearrangement, cannot yet be answered. A true explanation is not forthcoming for this sudden twist of nature.

The following report was prompted by Novak's² record of an unusual instance of intersex. Owing to the fact that our case of intersexuality presents much in common with his, the case herein reported was carefully followed for three years and the report is submitted together with important operative and histologic observations. We agree with Novak that when such case presentations of intersexuality are prepared in the proper manner they can add much clarity to the befuddled status of the intersexes. Speculative reports on "evidences of hermaphroditism" based on imagination, presumption and "wishful thinking," such as were reported up until a few years ago, are not only unscientific but misleading.

REPORT OF CASE

History.—A housewife aged 29, of American descent, appeared before one of us on June 6, 1938 with a vague complaint of

Fig. 5.—Section under low power magnification of the patient's normal fallopian tube.

abdominal pain. She also complained of headaches and dizziness. The fact that she had never menstruated did not seem to concern her much.

In her family history one interesting feature was the fact that her sister, two years younger than the patient, had also never experienced a menstrual period. A brother and two other sisters are married and have children.

The patient's infancy was normal and she experienced the routine childhood diseases as she approached adolescence. When she was 16 years of age she was examined by a local physician, vaginally and rectally, to ascertain the cause of her amenorrhea. Her family was told that the young girl was born somewhat different from other girls in that she did not possess a uterus. At about this time she commenced to suffer with backaches, abdominal cramps and headaches. She was still suffering with the abdominal cramps and headaches when first seen by us some thirteen years later. Her weight in adolescence had ranged between 95 to 100 pounds (43 to 45 Kg.). In the year

2. Novak, Emil: Sex Determination, Sex Differentiation and Intersexuality, *J. A. M. A.* **105**:413 (Aug. 10) 1935.

prior to our first seeing her she gained approximately 25 pounds (11.3 Kg.), making her weight about 125 pounds (56.7 Kg.) when she was first seen.

She had never had any sexual desire for the opposite sex and, although she had been married for eight years, she never experienced any sex urge toward her husband.

Fig. 6.—Section under low power magnification of gonad (testis) taken from patient, showing numerous interstitial cells.

She has few interests in life and does her own housework. She attends the movies occasionally and has a few women friends. She is quite attractive, has feminine charm and is of a very pleasant nature. She is neither bothered nor depressed about her amenorrhea; she would like to have children although she realizes that this is quite an impossibility. She dresses effeminately and with true girlish style. Her mentality is good.

Physical Examination.—General Appearance: The patient is white, of the Anglo-Saxon type, is 62½ inches (159 cm.) tall, weighs 124 pounds (56.2 Kg.) nude, and has normal and abundant blonde hair on her head and eyebrows but complete absence of axillary, pubic, perineal and anal hair. Her stature is slightly lordotic in the lumbosacral area of the spine, and her bony framework is light and thin. There is an excess of fat over the lower part of the abdomen and buttocks. The temperature, pulse rate and respiratory rate are normal.

Skin: Her skin is soft and pale, is covered with lanugo and has the soft tender touch similar to that of the skin of an infant. There are no acneiform lesions, lentigines, moles, warts or blemishes of any type. The skin about the vulva and rectum is scarcely pigmented and is of the same consistency as the rest of the skin. Her scalp is dry and the hair on her head is blonde and soft. When first seen, the breast areolas lacked pigmentation and the nipples were absent. The breasts were smaller than normal and the glandular consistency was abnormal.

Head and Neck: Her eyes are blue and the lashes are long. No abnormalities are noted except for two large central incisors in the upper set of teeth. Engelbach used this sign as being diagnostic of hypo-ovarianism.

Chest: Her bony thorax is small and delicate. The heart and lungs are essentially normal. The blood pressure is 90 systolic and 46 diastolic. Axillary hair and breast nipples are absent.

Abdomen: There is a layer of fat over the abdomen about 1½ inches in thickness. There are no scars, masses, tenderness, rigidity or pain on palpation. The abdominal aorta is easily palpable owing to an anterior curvature of the spinal column.

Extremities: The upper and lower extremities are fairly normal, although somewhat longer than usual.

Genitals: There is an absence of the normal pubic hair over the mons pubis. The labia majora and minora are smaller than usual. Although the clitoris is present and is normal in size, there is no erection of this organ on stimulation. There is also an absence of sexual excitation on palpation of the clitoris. The vestibule is normal and contains the openings of the urethra, vagina and accessory glands. There are no remnants of a hymen. The vagina, although its external opening is of normal size, is short in depth. On bimanual examination there is no cervix dipping into the vagina, nor is there a uterine body palpable. The ovaries and fallopian tubes are also not palpable. The posterior vaginal vault is so taut that it is difficult to feel much of anything through the vagina. A rectovaginal examination revealed no further information. Examination of the vagina with a speculum disclosed the similarity of the vaginal canal to a blind pouch. There is no cervix, os or anything resembling a cervix or os uteri. There is no opening into the abdominal cavity. The vaginal pH, as determined with nitrazine paper, ranged between 4.5 and 5.

Laboratory Reports.—The basal metabolic rate was minus 4; Wassermann reaction, negative; complete blood count, normal; urine, normal; blood sugar, 71 mg. per hundred cubic centimeters of blood; blood nonprotein nitrogen, 32 mg. per hundred cubic centimeters of blood; vaginal pH, between 4.5 and 5. Cellular study of vaginal washings did not seem abnormal; urinary estrogen and gonadotropic substance and blood estrogen and gonadotropic substance (serum) showed no increase over

Fig. 7.—Higher magnification showing immature seminiferous tubules in gonad of patient.

normal; a roentgenogram revealed no abnormalities; roentgen examination of the transabdominal pneumoperitoneum showed no signs of the presence of the uterus in the pelvis or abdomen.

Impressions.—At this time (before any therapy was started in 1938) the impressions gained were as follows: (1) primary

hypo-ovarianism, (2) congenital absence of uterus, (3) absence of breast nipples, (4) absence of axillary, pubic, perineal and anal hair.

At this time, the case was first reported in the literature as being illustrative of primary hypo-ovarianism with congenital absence of the uterus.³ For a period of eighteen months following the first report she was carefully watched and studied. In order to stimulate her libido and to attempt to render her life more normal, she was given estrogenic substances⁴ and later diethylstilbestrol.⁵ These substances were hugely successful in increasing the size of her breasts and nipples and in stimulating a new sense of sexual desire not previously experienced.

All during this time she continued to complain of the vague pain in the lower part of the abdomen, which at times became more severe directly over McBurney's point. This manifestation was considered separate from her other disorders and was assumed to be due to a mild form of recurrent appendicitis. She was cautioned that if some day she should experience a severe attack of this pain her appendix would have to be

Fig. 8.—Ductus deferens-like structure which was closely associated with the testis.

removed and at the same time inspection of the pelvic organs would be undertaken.

On March 25, 1940, after all estrogenic therapy had been discontinued for about two months, she appeared at the office of one of us with a severe right-sided abdominal pain. The long-awaited opportunity for appendectomy and exploratory laparotomy was at hand. She was accordingly admitted to the Jewish Memorial Hospital, where she was soon operated on.

Operation (Gynecology Service of Dr. Edward Hoenig).—A right rectus incision was made and the appendix, which was hyperemic and inflamed, was located. It was excised by the clamp and cautery method. The pelvis was next explored and a most unusual peculiarity presented itself (fig. 1): The bladder was found but there was no uterus in relation to it. Instead,

extending upward and laterally from the bladder on each side of the pelvis was a ligamentous cord, the upper end of which was attached to a small muscular organ about the size of a chestnut. These cords resembled bilateral rudimentary uteri. From each of these small bodies a thin fold extended to the lateral pelvic walls. These were probably vestigial broad ligaments. Within the broad ligaments and on each side was what appeared to be a fallopian tube in close association with each muscular body. Lying within the upper portion of each of the broad ligaments was a gonad. These gonads were similarly coated with a whitish capsule and were attached to the upper poles of the rudimentary uteri. There were no graafian follicles present in either gonad and the gonads seemed to be quite peculiar and atrophic. The uppermost ends of the broad ligaments were marked by clusters of small cystic nodules. The entire mass on the right side was removed for study. The other side was left intact, since we felt that total castration could do no good. Moreover, it was quite possible that even if a gonad appeared atrophic it might still have some endocrine function.⁶ The department of pathology examined the specimen and its interesting and unusual observations are here reported.

Pathologic Examination.⁷—Gross: The specimen consisted of a V shaped mass measuring about 3 cm. in length in one axis and about 4 cm. in the other (fig. 2). The external surface was covered with a somewhat thickened and smooth serosa. A thin walled cyst, measuring about 0.5 cm. in diameter, was attached to one end of the specimen. On section through the smaller axis a whitish mass with somewhat fibrous structure could be seen. On section through the other extremity of the specimen the cut surface showed a rather thick, grayish white capsule and grayish red stroma. A rounded yellowish area measuring about 2 mm. in diameter was present in this portion of the specimen, the cut surface of which was smooth. Attached to the longer axis was a fallopian tube which showed externally and on section no gross pathologic condition.

Microscopic: Sections from the thick musculature of the organ suggested an atypical uterus, owing to the presence of intertwining, closely placed, rather hypertrophic bundles of smooth muscle with distinct simulation of the uterine wall. The included blood vessels showed sclerosis and thickening. No endometrium was included in the sections.

Section through the fallopian tube (fig. 3) showed folded mucosa with characteristic ciliated epithelium and muscle structure. In the wall was some aberrant glandular tissue with adjacent closely placed muscle tissue. One area showed a large cystic space with low cuboidal epithelium resembling a hydatid.

Section of a gonad showed typical undifferentiated immature testicle structure with considerable intervening fibrosis (fig. 4). The capsule corresponding to the tunica albuginea was thickened and showed some smooth muscle. The bulk of the tissue was occupied by seminiferous tubules without differentiation of lining epithelium (fig. 5). The cells showed columnar arrangement with orientation at the nuclei. In none of the tubules could any attempt at differentiation or spermatogenesis be seen. In the stroma, wide islands of interstitial cells were prominent. These cells contained considerable lipochrome. Sinusoidal areas with an erectile appearance were also present in the stroma of the gonad. No ovarian stroma was seen in any of the sections.

One of the sections close to the gonad showed tissue resembling ductus deferens structure (fig. 6) by close approximation of developed smooth muscle and central epithelial lining.

SUMMARY

A patient exhibiting unusual intersexuality had all the aspects of a female but her gonads were definitely abnormally retained immature testes, and there was complete absence of ovarian tissue. Sufficient numbers of complete reports of such cases, when carefully studied, may be capable of eventually explaining the etiology of such unnatural switches in nature.

3. Weisman, A. I.: Complete Absence of the Uterus, *M. Rec.* 150: 392, 1939.

4. Weisman, A. I.: Breast Development from Estrogenic Hormones, with Report of a Case of Primary Hypo-Ovarianism, *M. Rec.* 151:391, 1940.

5. Weisman, A. I.: Rapid Breast Changes from Stilbestrol, *Clin. Med. & Surg.* 48:146, 1941.

6. Despite the fact that one gonad was left intact, the patient has since commenced to suffer with severe hot flushes that are typical of the menopause. Repeated and large doses of estrogenic therapy have been necessary to control these attacks since the operation.

PROGRESSIVE SUBCORTICAL ENCEPHALOPATHY

(ENCEPHALITIS PERIAXIALIS DIFFUSA; SCHILDER'S DISEASE)

JOHN J. O'DONNELL, M.D., ERIE, PA.

The following conditions are rarely if ever found in combination, namely a rare disease, a fairly exact measurement of intelligence before and after the onset of the disease and the confirmation of diagnosis at autopsy. All these conditions are present in the case herewith reported.

REPORT BY SCHOOL PSYCHOLOGIST

Zoe I. Hirt, school psychologist of the child study department, Erie, Pa., contributed the following history, obtained from the mother of the patient, E. S.:

The father was an alcoholic. The mother had pneumonia when seven months pregnant. She was threatened with an abortion and spent two weeks in bed. The child was born at full time, a blue baby. He had respiratory difficulties until his tonsils and adenoids were removed at the age of 3 years. At the age of 4 years he had infected ears and was treated in the hospital for two weeks. At 6 he fell from a garage roof and broke one of his arms just below the shoulder. His mother expressed the belief that his head was injured by the fall. A year later he was struck on the head by a horseshoe. The blow left a deep cut which was slow to heal. In the spring of 1939 he had severe ivy poisoning.

In November 1938 when the boy took the Kuhlmann-Anderson group intelligence tests with his fifth grade class he ranked second among 26 pupils, his intelligence quotient on that scale being 107. His conduct in school was excellent and his personal appearance good.

On June 11, 1940 the assistant principal of East High School sent him in for a psychologic examination because of his undesirable conduct. The complaints were frequent truancies, stubborn refusal to participate in class activities and recitations, failure to prepare and hand in assignments for out of class study, unwillingness to take part in classroom activities, disorderly conduct in the school corridors, remaining away from home until late at night, wandering aimlessly around the streets, destructiveness at home and outside, untidiness at meals, pushing his food from his plate and extreme restlessness.

On examination the boy was neat in appearance but had a shuffling gait and was restless, shifting his position continually from the back of his chair to the edge of the seat and rubbing and scratching his arms and wrists. Every little while he would hold the index finger of his right hand in front of his mouth and blow against it. His speech was thick, and at times he stuttered. Verbal responses were slow. Questions had to be repeated, sometimes over and over. When asked to explain his undesirable conduct in school he said "I want to fail; I can't do seventh grade work; it's too hard."

Form L of the 1937 revision of the Stanford-Binet scale was used to investigate his mental equipment on June 11. He succeeded with all the tasks at year 7 and above that level with additional items scattered thinly as far as year 12. He lacked barely one month of being 13, and his only successes at the 12 year level were in two vocabulary items. He could not retain more than five digits for immediate recall after he heard them. He could not read a word of the little paragraph printed under year 10 on the test scale. It was obvious that he could not see the words, so a first reader selection in large type was placed before him. After much effort, holding the page close to his eyes, he read "A boy ran along" instead of "A boy had a dog." He could not keep his place on the page as he continued to read the little selection. He said that he should receive a nickel in change if he gave a storekeeper 15 cents in payment for a 12 cent article. He thought that his change should be 14 cents from a quarter if he bought some-

thing costing 4 cents. He repeated the same five or six words over and over when asked to name all the different words he could think of in a minute. He seemed totally lacking in critical judgment. The sum of his correct responses in the test gave him an intelligence quotient of 63.

HOSPITAL REPORT

E. S. was admitted to Hamot Hospital Oct. 13, 1939 with cellulitis of the floor of the mouth. He had had an upper molar on the right side extracted five days before. The day after extraction he began to have swelling on the under surface of the mandible on the right side. The swelling gradually became enlarged and though not inflamed was extremely tender to touch. The next day he began to have chills and weakness. His mother applied ice bags to his jaw and forced fluids. The chills had persisted, but the swelling on the jaw had not altered much since three days before admission.

The Wassermann and Kline reactions of the blood were negative and the blood counts normal. The temperature on admission was 102.2 F., but it rapidly subsided under treatment with 15 grains (0.9 Gm.) of sulfanilamide and 10 grains (0.6 Gm.) of sodium bicarbonate every four hours.

The patient was discharged as cured on October 23.

On June 12, 1940 he came to the neuropsychiatric clinic, and he was admitted to the ward for study. He had an unsteady gait, failing vision and a dull mentality.

On physical examination he appeared well developed and nourished. Neurologic examination revealed that the pupils were regular, dilated and reactive to light and in accommodation. The visual acuity admitted by the patient was 20/100 in each eye. Tests of refraction revealed that there was small hyperopic astigmatic correction, and on prodding the examiner could get the patient to read with a 20/50 acuity in each eye. Fundus examination gave normal results throughout. There was very pronounced concentric contraction of the visual fields but no significance in the boy's responses. Examination of the eyes revealed nothing of definite significance from the diagnostic standpoint.

The speech was slow. There was no restriction of the tongue or the palate and no stiffness of the neck. The tendon reflexes were increased. The epicritic and deep sensibility was increased. There was no Babinski, Gordon, Oppenheim or Chaddock reflex, but Romberg's sign was present. The gait was spastic. There were incoordination of the arms and legs and past pointing. The abdominal and cremasteric reflexes were normal. Kernig's sign was not present. The vibratory sense was normal. The patient was unable to do the heel to shin and toe to finger tests.

On examination of the spinal fluid the pressure was 6 and the cell count 4. There was a slight increase in the globulin content. The Wassermann reaction was negative. The blood showed a hemoglobin content of 86 per cent, 6,700 leukocytes and 5,320,000 erythrocytes. The color index was 0.8. The Wassermann and Kline reactions of the blood were negative.

Roentgen examination revealed that the bones of the skull were of normal density and thickness. No abnormal shadows were seen, and there was no evidence of increased intracranial pressure. The sella turcica was small and of the enclosed type. Nothing was seen to indicate pressure or change in the bone in this region. The sphenoid sinus was large.

With the foregoing data, tumor of the brain could be ruled out with some degree of certainty. The mental deterioration, failing vision and spastic gait being taken into consideration, a diagnosis of progressive subcortical encephalopathy (Schilder's disease, or encephalitis periaxialis diffusa) was made. The boy was sent home June 17.

During the interval between the patient's discharge and readmission to the hospital I saw him at home once a week. The vision became progressively worse, and there was more dulling of intelligence.

He was sent into the hospital on August 4. On admission he was apparently unconscious, the neck was rigid and retracted

The laboratory studies and autopsy were done by Dr. E. L. Armstrong, the ophthalmic examination by Dr. James Delaney and the roentgen examination by Dr. B. Swayne Putts.

and the whole body would jerk most of the time. The eyes were open but sightless. The boy would cry from pain.

At this time the deep tendon reflexes were lost. Kernig, Babinski, Gordon, Oppenheim and Chaddock reflexes were present bilaterally. Opisthotonos was present at times and incontinence of the bowels and the bladder. Stertorous respiration was constant. Only a small amount of fluid was taken. The patient was unable to swallow solids. The temperature was between 99 and 104 F., and he was in a stupor at all times.

The only medication given was morphine to relieve pain. Death occurred on August 19.

AUTOPSY REPORT

External Examination.—The body was emaciated. The height was 63 inches (160 cm.) and the weight approximately 80 pounds (36.3 Kg.). The superficial layers of the skin of the trunk were raised in tiny blebs that brushed off easily when the skin was rubbed. These blebs were filled with clear watery fluid. No edema or jaundice was noted and no enlargement of the superficial lymph nodes. No scars or marks of injury were seen on the body surface. The joints throughout the body appeared fixed, apparently from prolonged muscle spasm.

Eyes: The pupils were unequal but regular, and both were dilated. The left pupil was 7 mm. and the right 8 mm. in diameter.

Internal Examination.—**Brain:** On removal of the skull cap the vessels of the meninges were seen to be everywhere injected. No gross hemorrhage was present and no free exudate was seen over the surface of the brain. On serial section the white matter throughout the brain showed dilated vessels and apparently minute areas of hemorrhage. No gross degeneration or abscess formation was noted.

The dura was stripped from the base of the skull and the sinuses and middle ears examined. The mastoid cells and the middle ear on the left side were filled with a yellowish mucopurulent secretion. The right middle ear and mastoid cells were dry, as were the bony sinuses.

Thorax: On removal of the chest wall both lungs lay free. There was no free fluid in the pleural cavities. The lungs were crepitant throughout and showed no evidence of consolidation. No hemorrhage was noted beneath the pleura.

Heart: The amount of pericardial fluid was not increased. Examination of the myocardium and the heart valves revealed nothing remarkable.

Abdomen and Pelvis: Gross examination of the organs in the abdomen and the pelvis revealed nothing definitely pathologic.

Bacterial Flora: Smears of material from the left mastoid cells showed many staphylococci and numerous short chain streptococci. Cultures of material from the brain surface were sterile, as were cultures of the blood.

Microscopic Examination of Brain.—Fourteen blocks were taken from different areas in the cerebral and cerebellar cortex. In examination of these sections the following microscopic changes produced by progressive subcortical encephalopathy were noted:

1. The myelin sheaths of the white matter were destroyed and in places disintegrated. This was particularly noticeable in the sections of cerebral cortex and at a few points was noted to extend into the margins of the gray matter. Multiple foci were observed.

2. The perivascular spaces were greatly enlarged from retraction of the surrounding neuroglial tissue.

3. There were diffuse perivascular accumulations of lymphocytes, with scattered plasma cells. In some sections this perivascular infiltration was dense and was seen not only in the vessels lying deep in the white matter but in the meninges.

The anatomic diagnoses were (1) hyperemia and engorgement of the meningeal vessels and (2) the presence of free pus in the left mastoid cells and the left middle ear. The cause of death was progressive subcortical encephalopathy.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.
THEODORE G. KLUMPP, M.D., Secretary.

HALOGENATED VEGETABLE OILS FOR BRONCHOGRAPHY AND THE PROBLEM OF LIPID PNEUMONIA

The manufacturer of a preparation of iodine and chlorine in peanut oil for intratracheal administration as a bronchographic medium has recently called attention to the following statement occurring in the editorial "Lung Irritation Following the Use of Certain Oil Preparations" (THE JOURNAL, April 26, 1941, p. 1911): "Several of the vegetable oils, notably croton oil, castor oil and peanut oil, are exceedingly active irritants of tissues." The manufacturer points out that this statement has led to inquiries from physicians which indicate that members of the medical profession do not understand that this statement does not apply to refined grades of peanut oil from which irritating unsaturated fatty acids have been eliminated, such as the completely saturated halogenated product which it manufactures.

The editorial containing the statement in question was based on a previous report by Dr. Paul R. Cannon (The Problem of Lipid Pneumonia, THE JOURNAL, Dec. 21, 1940, p. 2176), published under the auspices of the Council on Pharmacy and Chemistry, which deals primarily with the promiscuous intranasal use of oily inhalants, particularly those containing liquid petrolatum. Regarding the manufacturer's point that saturated peanut oil is not as irritating as the crude unsaturated oil, Dr. Cannon explains that, while it appears reasonable that complete saturation with removal of free fatty acids should eliminate some of the irritating properties of this and other vegetable oils, the problem has not been adequately studied. He emphasizes, however, that this problem should not be confused with that of lipid pneumonia resulting from the constant use of nasal oil drops, since, even if slightly irritating, halogenated oils for bronchographic study are used relatively infrequently and then only under the supervision of a roentgenologist.

The Council concurs with the view expressed by Dr. Cannon that the problem of lung irritation from the use of oils other than petrolatum needs further study, especially from the standpoint of inhalant preparations which are subject to unsupervised use by the public.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary.

EPINEPHRINE (See New and Nonofficial Remedies, 1941, p. 251).

SOLUTION OF EPINEPHRINE HYDROCHLORIDE 1:1,000-LAKESIDE.—A brand of solution epinephrine hydrochloride-U. S. P. containing chlorobutanol 0.5 per cent and sodium bisulfite 0.1 per cent in physiological solution of sodium chloride, saturated with carbon dioxide.

Manufactured by The Lakeside Laboratories, Inc., Milwaukee.
Solution of Epinephrine Hydrochloride 1:1,000-Lakeside, 1 cc. ampule.
Solution of Epinephrine Hydrochloride 1:1,000-Lakeside, 30 cc. rubber stoppered vial for parenteral administration.

McKESSON'S NATURAL VITAMINS A AND D IN OIL, 6 CC.—A concentrate of vitamins A and D prepared from medicinal cod liver oil, the concentrate containing not less than 60,000 U. S. P. units of vitamin A and not less than 10,000 U. S. P. units of vitamin D per gram.

Actions and Uses.—It possesses the therapeutic properties recognized for the vitamins present in cod liver oil.

Dosage.—Six drops per day. Larger dose as prescribed by the physician.

Manufactured by the International Vitamin Corporation, New York. (McKesson & Robbins, Inc., Bridgeport, Conn., distributor.) The vitamin D concentrate used is made under U. S. patent No. 1,690,091 (Oct. 30, 1928; expires 1945).

SATURDAY, DECEMBER 27, 1941

A CALL TO THE MEDICAL PROFESSION

The nation is at war. The Congress has passed an amendment to the Selective Service Act which will call for registration of every man up to the age of 65 and which will place all men under 45 years of age subject to service at the order of the Selective Service boards.

The Procurement and Assignment Service for Physicians, Dentists and Veterinarians was established by order of the President on October 30. Thus the medical profession itself aids in determining proper distribution of the medical profession in supplying the needs of the armed forces and maintaining medical service to civilian communities, public health agencies, industrial plants and other important needs.

At a meeting of the Procurement and Assignment Service held in Chicago at the headquarters of the American Medical Association on December 18 jointly with the Committees on Medical Preparedness of the American Medical Association, the American Dental Association and the American Veterinary Medical Association, plans were drawn for making immediately available to the United States Army and Navy Medical Corps the names of physicians who wish to be enrolled promptly in the service of the government in this emergency.

On the opposite page is published a blank by which every physician may at once place his name with the Procurement and Assignment Service as one who is ready to serve the nation as the need arises. If you wish to make yourself available for classification, fill out this blank and send it at once to Dr. Sam F. Seeley,

Executive Director of the Procurement and Assignment Service. When these blanks are received, they will be classified and checked with the information available in the national roster of physicians at the headquarters of the American Medical Association.

For two thousand and nine counties in the United States, lists have been prepared indicating physicians who are engaged in necessary civilian projects, public health services or educational activities from which they cannot be spared. Shortly the rest of the counties will have such lists available.

In each of the corps areas covering the United States a committee is being established, including representatives of medical, hospital, educational, dental and veterinary activities. In the individual states, committees of medical, dental and veterinarian professions are being established through which the corps area committees will exercise their functions. In each county also local committees will provide accurate information regarding the status of each member of the profession concerned.

The raising of the Selective Service age from 28 to 45 will place a great number of additional physicians in the category of those on whom the nation may call as their services are needed. Estimates indicate that some sixty thousand physicians thus become available for service and that forty-two thousand dentists under the age of 45 also become subject to call. By enrolling with the Procurement and Assignment Service immediately, utilizing the blank on the opposite page, all physicians, but particularly those under 45 years of age, insure to every extent possible assignment to the type of service for which they are best fitted. They avoid thus also the possibility of unclassified service with the United States Army during the period that may be necessary following selection by the Selective Service before the commission can be secured. A physician called by the Selective Service who has not enrolled or who is not on a reserve list obviously serves without a commission during the time that necessarily elapses before a commission is secured. In future issues of THE JOURNAL announcements will be made regularly of the numbers of those who enroll and of the extent to which the immediate needs of the Army, Navy and other government agencies are being supplied.

ENROLMENT FORM FOR PROCUREMENT AND
ASSIGNMENT SERVICE FOR PHYSICIANS

Dr. Sam F. Seeley, Executive Officer
Procurement and Assignment Service
New Social Security Building
4th and C Streets S.W.
Washington, D. C.

Dear Doctor Seeley:

Please enroll my name as a physician ready to give service in the Army or Navy of the United States when needed in the current emergency. I will apply to the Corps Area commander in my area when notified by your office of the desirability of such application.

Signed _____

1. Give your name in full, including your full middle name:
2. The date of your birth:
3. The place of your birth:
4. Are you married or single?
5. Have you any children? If so, how many?
6. Do you believe yourself to be physically fit and able to meet the physical standards for the Army and Navy Medical Corps?
7. Have you filled out previously the questionnaire sent to all physicians by the American Medical Association?
8. When and where were you graduated in medicine?
9. In what state are you licensed to practice?
10. Do you now hold any position which might be considered essential to the maintenance of the civilian medical needs of your community? If so, state these appointments:
11. Have you previously applied for entry into the Army or Navy Medical Service? If so, state when, where and with what result (if rejected, state why).

Fill out this blank, tear out and send to Dr. Sam F. Seeley at the above address.

CONGRESS ACTS TO SAFEGUARD USERS OF INSULIN

Congressional action on legislation to protect the users of insulin was completed on December 19. Prompt action was necessary because the patent on insulin, held by the University of Toronto, under which patent adequate standards of purity and strength have been maintained, expired on December 23.

The legislation that has been enacted amends the Federal Food, Drug and Cosmetic Act by declaring a drug to be misbranded if it is, or purports to be, or is represented as a drug composed wholly or partly of insulin unless (1) it is from a batch with respect to which a certificate or release has been issued under regulations to be promulgated by the Federal Security Administrator and (2) such certificates or release is in effect with respect to such drug. The Federal Security Administrator is directed to provide for the certification of batches of drugs composed wholly or partly of insulin. A batch of any such drug, the legislation provides, shall be certified if the drug has such characteristics of identity and such batch has such characteristics of strength, quality and purity as the Administrator prescribes in such regulations as necessary adequately to insure safety and efficacy of use. Prior to the effective date of such regulations, the Administrator is authorized, in lieu of certification, to issue a release for any batch which, in his judgment, may be released without risk as to the safety and efficacy of its use. Regulations providing for such certification must, among other things, contain provisions prescribing (1) standards of identity and of strength, quality and purity, (2) tests and methods of assay to determine compliance with such standards, (3) effective periods for certificates and other conditions under which they shall cease to be effective as to certified batches and as to portions thereof. The regulations, the legislation provides, shall prescribe no standard of identity or of strength, quality or purity for any drug different from the standard of identity, strength, quality or purity set forth for such drug in an official compendium such as the United States Pharmacopeia or similar publication. The Pharmacopeia has adopted standards for insulin.

In explaining the purpose of the legislation and the urgency of the need for immediate action, Representative Lea of California made this statement on the floor of the House of Representatives:

There is an emergency situation that caused our committee to act on this bill at the present time. The report before the House represents the unanimous opinion of the committee.

The patent on insulin expires on the 23d of this month. Control of the manufacture of insulin is in the hands of the University of Toronto. The patent is owned by the University of Toronto, and manufacturers in the United States act under license from the committee on insulin of that university.

Control of insulin quality by the University of Toronto has been most commendable. That control has been on a nonprofit, humane and scientific basis. It has required that all manufacturers comply with the standards set up by the committee

on insulin in order to engage in its manufacture or sale. This control was through ownership of the patent right.

On expiration of the patent, present control over the situation will cease and manufacturers in this country would be at liberty to manufacture and place insulin on the market in disregard of that uniform standard of quality and strength that are so essential for the protection of users of insulin.

Over one million people in the United States are now under insulin treatment. It is estimated they are spending about \$15,000,000 a year for this remedy. Ordinarily the doctor gives the patient a prescription, who after that buys from any drug store available. So far the afflicted person has had the protection that is given by a uniform standard and strength under the restrictions imposed by the owners of the patent.

The effect of insulin is such that injury and death may result from taking too much or too little. The peril to the public that would ensue from the lack of a uniform standard would be primarily due to the variation and uncertain quality as to strength and purity unless its standardization is assured by the federal government acting through the Food and Drug Administration.

Under the amendment here proposed to the Food, Drug and Cosmetic Act, every batch of insulin would be submitted to tests to assure its freedom from infection, its purity and strength. Each batch would be subject to approval of the Food and Drug Administration and rejected if not of a properly standardized quality. By this means all users of insulin suffering from diabetes can be assured of the quality, the standard, strength and purity of their purchases.

The procedure required in making tests, the adoption of regulations to control such tests and the certification thereof by the Food and Drug Administration will conform to the practice that already prevails in requiring such tests, and issuing such certificates as to certain coal tar products.

THE FORMATION OF URINE

The early studies of Bowman, who maintained that the glomeruli of the kidney acted as filters and the cells of the tubules as secreting agents, together with the work of Heidenhain, who championed the conception that the formation of urine was entirely a secretory process, and the ideas of Ludwig, who thought that a process of absorption might occur in the tubules of the kidney, contribute interesting early chapters in the story of renal function. The more modern view so well expressed by Cushny,¹ according to which the excretion of urine involves simple filtration in the glomeruli coupled with selective reabsorption in the tubules, is now familiar. The classic work of Wearn and Richards,² who some two decades ago collected glomerular urine directly from Bowman's capsule in the living frog kidney by means of a capillary pipet, opened a new route of attack on the problem of glomerular and tubular function. Since that time methods have been developed for the collection of fluid from single tubules of the amphibian kidney, and the analysis of the minute amounts of fluid collected has been accomplished. The results of these studies has lent powerful support to the filtration-reabsorption theory of urine formation.

The mammalian kidney has now been successfully used in this type of study. In recent reports, Walker

1. Cushny, A. R.: *The Secretion of the Urine*, ed. 2, New York, Longmans, Green & Co., Ltd., 1926.

2. Wearn, J. T., and Richards, A. N.: *Observations on the Composition of Glomerular Urine, with Particular Reference to the Problem of Reabsorption in the Renal Tubules*, *Am. J. Physiol.* 71: 209 (Dec.) 1924.

and his co-workers³ describe their interesting experiments on the kidneys of anesthetized animals, particularly rats and guinea pigs. These investigators were able to collect amounts of fluid sufficient for quantitative microanalysis from a single glomerulus, proximal tubule and distal tubule. By a procedure involving microdissection of the nephrons, the precise site of the collection could be identified. Unfortunately, only in guinea pigs could glomeruli be found which were accessible for study. Certain portions of the proximal and distal tubules in guinea pigs, rats and other mammals are conveniently located with regard to the possibility of collecting fluid from them. Analyses of glomerular fluid reflect the filtering function of the glomerulus. While little or no protein was found in the glomerular filtrate, it did contain reducing substances and creatinine in concentrations similar to those existing in blood plasma. The reducing substances are reabsorbed as fluid flows through the proximal tubule. The site of dextrose absorption is therefore the same in the mammalian and the amphibian kidney. At least two thirds of the fluid also appears to be resorbed within the proximal tubule. As pointed out by Walker and his co-workers, this is the reverse of the situation demonstrated in amphibians and it supports the suggestion of Smith that "in the mammal a great part of the water might be reabsorbed in the proximal tubule."⁴ While fluid reabsorption in the mammalian tubule is accomplished without any increase in the osmotic pressure of the fluid remaining within the tubule, it is not by any means a purely passive reabsorption of unchanged glomerular filtrate. Proximal tubular fluid possesses a distinctly higher percentage of chloride than does plasma. The ratio of the chloride concentration in the former fluid to that in plasma appears to reach an average of 1.4 in the first third of the proximal tubule and to remain at that point without further increase throughout the second third of this segment. These observations are apparently indicative of preferential reabsorption of another ion, presumably bicarbonate, in the proximal tubule. On the other hand, since most of the bladder urine specimens in the experiments were found to be hypotonic to plasma with respect to chloride, some further portion of the nephron must reverse the concentration ratio of the proximal segment and preferentially reabsorb the chloride ion.

The recent work of Walker and his associates on the collection and quantitative analysis of glomerular and tubular fluid from mammalian kidneys forms a logical extension of the work initiated by Richards and his co-workers on amphibians. The continued prosecution of these studies will serve further to elucidate problems associated with renal function.

Current Comment

HEALTH ACHIEVEMENTS IN WISCONSIN

Various state medical societies have been undertaking the education of the lay public in health from different approaches. In previous issues of *THE JOURNAL* reference has been made to the program of the California Medical Association¹ and the programs of the medical societies of New York² and Georgia.³ In Wisconsin the approach has been emphasis on the health achievements within the state. The Wisconsin State Board of Health has long been advertising Wisconsin as the third healthiest state in the United States on the basis of ratings by the National Resources Board. The state medical society has made this rating the keynote of a pamphlet⁴ prepared with the cooperation of the state board of health and the state industrial commission. In this pamphlet, illustrated with pictorial statistics, photographs, vignettes and montages, are set forth health achievements in the state such as favorable rates of time lost from industrial jobs, addition of nineteen years to the average life expectancy at birth, over 99 per cent of babies delivered by physicians, low infant and maternal death rates, decline of communicable diseases, availability of hospital facilities, virtual conquest of typhoid, inspections of barber shops, beauty parlors, tourist cabin and summer resort inspections, and industrial and community sanitation. Medical education, postgraduate education and nursing education are dealt with in another section, as is registration of births and deaths. The third section of the booklet deals with unsolved problems in communicable disease control, accident prevention, community and industrial sanitation, heart, cancer, cerebral hemorrhage and nephritis. Emphasis is placed on the availability of physicians, who are at least as easily available as other necessary community facilities, except in three areas all of which are so sparsely populated that no physician could make a living there and even subsidies from local funds are but "a theoretical solution." The pamphlet closes with brief descriptions of eleven cooperative projects of the State Medical Society of Wisconsin with state and public agencies. Going a step further, a film strip has been developed consisting of one hundred frames, which sets forth the same general facts as those in the brochure and under the same title. Accompanying this film strip is an outline for an accompanying lecture.⁴ This film strip is to be made available throughout the state for presentation by county medical societies or under their auspices to lay audiences. More and more the diversity of approach to lay health education by medical societies in various states and counties demonstrates original methods and emphasizes again the importance of free and uninhibited enterprise in an independent medical profession.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS, VETERINARIANS

At a meeting in Chicago of the board of the Procurement and Assignment Service with the Committees on Medical Preparedness of the American Medical Association, the American Dental Association and the American Veterinary Medical Association, a definite organization was completed for the functioning of this service in relationship to needs of professional personnel in the war.

PHYSICAL REQUIREMENTS FOR PHYSICIANS IN SERVICE

The Procurement and Assignment Service will make available shortly through publication in the periodicals of the professions concerned a tabulation of the physical requirements for physicians applying to any of the federal services.

EVALUATION OF PHYSICIANS THROUGH COUNTY MEDICAL SOCIETIES

More than two thousand county medical societies have already made available ratings of physicians available in such counties as regards their employment in essential services and their availability for the Army and Navy Medical services. Steps will be taken to speed up the completion of similar evaluations in the remaining counties.

QUESTIONNAIRE

Approval was given to the immediate publication in the professional periodicals of a questionnaire addressed to all members of the medical profession urging them to enroll at once with the Procurement and Assignment Service so as to make available immediately a pool of physicians from whom applicants for commissions might be drawn promptly. The immediate needs of the Army are for men in the grades of lieutenant and captain—that is to say, men particularly under the age of 45.

THE NATIONAL ROSTER

A conference was held with representatives of the National Roster, which is a subsidiary of the National Resources Planning Board. Arrangements were made for joint action with the Budget Committee in Washington to secure the necessary funds for operation of the National Roster covering the medical profession and for the regional office in the headquarters of the American Medical Association.

CORPS AREAS

Dr. James A. Paullin described the methods by which evaluation has been made of all men in the Fourth Corps Area and also the method by which ratings have been given to specialists.

Approval was given to the constitution of committees in each of the corps areas and associated naval districts to function as advisory to the corps area commander, the committee to consist of a chairman who will be the corps area representative of the Committee on Medical

Preparedness of the American Medical Association, one physician representing medical education, one representing the hospital organizations, two physicians selected at large, two dentists and one representative of the veterinary profession. The chairmen nominated for the various corps areas are as follows:

- First—DR. W. G. PHIPPEN, Salem, Mass.
- Second—DR. A. W. BOOTH, Elmira, N. Y.
- Third—DR. A. M. SHIPLEY, Baltimore.
- Fourth—DR. EDGAR GREENE, Atlanta, Ga.
- Fifth—DR. E. L. HENDERSON, Louisville, Ky.
- Sixth—DR. CHARLES H. PHIFER, Chicago.
- Seventh—DR. ROY W. FOUTS, Omaha.
- Eighth—DR. SAM E. THOMPSON, Kerrville, Texas.
- Ninth—DR. CHARLES A. DUKES, Oakland, Calif.

Other physicians nominated to these corps area boards include:

- First—DR. DEERING G. SMITH, Nashua, N. H.; DR. LUCIUS KINGMAN, Providence, R. I.
- Second—DR. S. J. KOPETZKY, New York; DR. W. J. CARINGTON, Atlantic City, N. J.
- Third—DR. C. H. HENNINGER, Pittsburgh; DR. HUGH H. TROUT, Roanoke, Va.
- Fourth—DR. ALFRED A. WALKER, Birmingham, Ala.; DR. EDWARD H. JELKS, Jacksonville, Fla.
- Fifth—DR. ROBERT CONARD, Wilmington, Ohio; DR. LARUE CARTER, Indianapolis.
- Sixth—DR. J. MILTON ROBB, Detroit; DR. STEPHEN E. GAVIN, Fond du Lac, Wis.
- Seventh—DR. F. L. LOVELAND, Topeka, Kan.; DR. ROBERT L. PARKER, Des Moines, Iowa.
- Eighth—DR. HOLMAN TAYLOR, Fort Worth, Texas; DR. JOHN W. AMESSE, Denver.
- Ninth—DR. JOHN FITZGIBBON, Portland, Ore.; DR. JOHN H. O'SHEA, Spokane, Wash.

A regional office is to be established in each corps area for the maintenance of information, for supervision of the state committees and to act as a consulting body on all matters relating to the functions of the Procurement and Assignment Service in the corps area. The following dentists were recommended for appointment:

- First—DR. PHILIP ADAMS, Boston; DR. FRANK W. ROUNDS, Boston.
- Second—DR. WILLIAM MCG. BURNS, Brooklyn; DR. ALLAN T. NEWMAN, New York.
- Third—DR. LUCIAN BRUN, Baltimore; DR. HARRY BEAR, Richmond, Va.
- Fourth—DR. CLAUDE R. WOOD, Knoxville, Tenn.; DR. RALPH R. BYRNES, Atlanta, Ga.
- Fifth—DR. EARL LOWERY, Columbus, Ohio; DR. WENDELL POSTLE, Columbus, Ohio.
- Sixth—DR. LEO KREMER, Chicago; DR. PAUL H. JESERICH, Ann Arbor Mich.
- Seventh—DR. F. A. PIERSON, Omaha; DR. A. W. BRYAN, Iowa City.
- Eighth—DR. H. G. DUCKWORTH, San Antonio, Texas; DR. FRED C. ELLIOTT, Houston, Texas.

Ninth—DR. B. C. KINGSBURY, San Francisco; DR. E. G. SLOMAN, San Francisco.

The following veterinarians were recommended for appointment:

First—DR. R. W. SMITH, Concord, N. H.
Second—DR. R. R. BIRCH, Ithaca, N. Y.
Third—DR. MARK WELSH, College Park, Md.
Fourth—DR. B. T. SIMMS, Auburn, Ala.
Fifth—DR. A. F. SCHALK, Columbus, Ohio.
Sixth—DR. WARD GILTNER, East Lansing, Mich.

Seventh—DR. H. D. BERGMAN, Ames, Iowa.

Eighth—DR. M. B. STARNES, Dallas, Texas.

Ninth—DR. C. M. HARING, Berkeley, Calif.

The names of the physicians representing medical education and those of the hospital organizations will be published later.

The technic was also described for supplying the names of physicians to appropriate governmental agencies according to the present methods of functioning of the Procurement and Assignment Service.

UNITED STATES CIVIL SERVICE COMMISSION NEEDS PHYSICIANS

The United States Civil Service Commission has issued a table showing the number of medical officers (Associate grade \$3,200 per annum) needed in the immediate future in federal agencies. The positions are those in the civil service, for which the Civil Service Commission has the responsibility of recruiting, rating and maintaining registers of qualified eligibles. The needs are, of course, expected to vary as vacancies are filled or new positions are open. Later statements may be required as changes occur (see civil service announcement No. 130 of 1941). The table shows the following needs:

Veterans' Administration	
Optional Branches:	
Tuberculosis	2
Neuropsychiatry	40
General medicine and surgery	40
Ear, eye, nose and throat	5
Roentgenology	3
Pathology	4
Urology	2
Orthopedics	2
Cardiology	1
Chest	1
	100
U. S. Public Health Service	
Optional Branches:	
General practice	37
Public health (general) or general practice	35
	72
Indian Service	
General practice	32
	32
Panama Canal Service	
General practice	15
Eye, ear, nose and throat	1
Pathology	1
	17
Total	219

* U. S. Children's Bureau..... 10

* Estimated need for calendar year 1942. Salary ranges \$3,200 to \$5,600 per annum. See civil service announcement No. 139 of 1941.

Requirements are:

Education.—Applicants for the Associate grade must have been graduated from a medical school of recognized (class A) standing with the degree of M.D. subsequent to May 1, 1930.

In determining the date of graduation of those physicians who have graduated from one of the medical schools which requires a one-year internship following the medical curriculum before conferring the degree of M.D., the commission, for the

purpose of this examination, will consider as the date of graduation the time when the fourth year curriculum was successfully completed and not the date following the internship.

The applications of graduates from foreign medical schools whose graduates are admitted to the examination of the National Board of Medical Examiners will be accepted.

Experience.—Subsequent to graduation, applicants must have had one year of internship, general rotating or in a special branch.

Age Limit.—Applicants must not have passed their fifty-third birthday on the date of receipt of application. The age limit does not apply to persons granted military preference because of military or naval service except that such applicants must not have reached the retirement age.

Physical Ability.—Applicants must be in sound physical health. Remediable defects or curable disease will not exclude a person from examination, but proof that such defects have been remedied or the disease, if any, cured must be received during the life of the eligible register before persons otherwise qualified may be considered for appointment under civil service rules.

Vision must be at least 20/30 (Snellen) in one eye, glasses permitted. The applications of persons who have uncorrected vision of less than 20/200 (Snellen) in that eye, corrected to meet the foregoing requirement, will be suspended and they will not be eligible for appointment until satisfactory evidence has been presented to the commission showing that there is no disease or defect of the eye other than an error of refraction.

Ordinary conversation must be heard at a distance of at least 15 feet with one ear.

For some of these positions, applicants must be at least 5 feet 4 inches in height. The height requirement will be waived for veterans. Vision without glasses must be at least 20/100 (Snellen) in one eye and 20/70 (Snellen) in the other eye and must be corrected to at least 20/40 (Snellen) in one eye and 20/30 (Snellen) in the other eye. Applicants must be able to distinguish basic or saturated colors (lantern, yarn or other comparable tests). Hearing must be 12 feet, each ear. Both upper and lower extremities must be present in their entirety with the exception of the loss of toes or fingers which will cause no disability in the performance of duties.

A rigid physical examination will be made by a federal medical officer or other duly licensed doctor of medicine before appointment. Persons who are offered appointment must pay their own expenses in reporting for duty. If, on reporting at the place of assignment, they are found ineligible because of physical defects, they cannot be appointed and no part of their expenses for returning home can be borne by the government.

MEDICAL UNITS FOR SAN FRANCISCO

At the request of Angelo J. Rossi, mayor of San Francisco, two medical catastrophe units were shipped to that city on December 15 by the Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York. Arrangements are under way to send similar first aid medical and surgical units to hospitals in Maine, Vermont, South Carolina and New York, in response to requests. The new policy of the Medical and Surgical Relief Committee of America is to concentrate

future activities on the furnishing of aid to American hospitals and other organizations where they require it for emergency use.

The Medical and Surgical Relief Committee of America is composed of some three hundred and fifty prominent physicians and surgeons. Its object is to make up shortages in surgical and medical supplies in America and, when necessary, to solicit donations for specific needs.

ORGANIZATION SECTION

OFFICIAL NOTES

THE ATLANTIC CITY SESSION

Special Exhibits on Fractures, Lame Backs, and Home and Hospital Delivery

The Committee on Scientific Exhibit announces that there will be three special exhibits at the Atlantic City session, as follows:

Special Exhibit on Fractures.—Presented by a committee composed of Dr. Kellogg Speed, Chicago, chairman; Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia.

Special Exhibit on Lame Backs.—Presented under the auspices of a committee composed of Dr. Frank R. Ober, Boston, chairman; Dr. Carl E. Badgley, Ann Arbor, Mich.; Dr. J. Archer O'Reilly, St. Louis; Dr. Arthur Steindler, Iowa City, and Dr. Philip D. Wilson, New York.

Special Exhibit on Home and Hospital Delivery.—Presented under the auspices of the Section on Obstetrics and Gynecology by a committee composed of Dr. Charles Edwin Galloway, Evanston, Ill., and Dr. Philip F. Williams, Philadelphia.

DOCTORS AT WORK BROADCASTS

Doctors at Work, the radio broadcast by the American Medical Association and the National Broadcasting Company, will continue uninterrupted through the holiday season.

The broadcasts are on the Red Network of the National Broadcasting Company and we are informed that approximately one hundred stations from coast to coast have signified their intention of taking the program.

The program features a dual theme, medical preparedness and "delay is dangerous." Under the first theme the relationship of doctors to the national emergency will be depicted, while under the second theme various medical situations and health situations in which delay may be disastrous to the patient will be illustrated.

As many as possible of the broadcasts are being relayed by short wave transmitters for rebroadcasting by the British Broadcasting Corporation, according to information received from the National Broadcasting Company.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 6251 has passed the House and Senate, amending the Federal Food, Drug and Cosmetic Act by providing for the certification of batches of drugs composed wholly or partly of insulin, the certification to be under regulations to be promulgated by the Federal Security Administrator.

Bills Introduced.—H. R. 6229, introduced, by request, by Representative Rankin, Mississippi, proposes to provide liberalized benefits for disabled American veterans of the World War and their dependents. This bill provides, among other things, that the Administrator of Veterans' Affairs shall receive and adjudicate claims for World War emergency officers' retirement according to provisions of the Act of May 24, 1928, and where entitlement is established the Administrator is authorized to

grant retirement as provided in that act. The benefits or privileges provided by the pending bill may not be denied because of failure to file claim within the period required by the 1928 act or because the former officer was not, prior to March 20, 1933, granted retirement pay. H. R. 6240, introduced by Representative Gillie, Indiana, provides that there shall be in the Medical Department of the Army, in addition to such assistants to the Surgeon General as are now authorized by law, an assistant with the rank of brigadier general, who shall be an officer of the Veterinary Corps. H. R. 6241, introduced by Representative Rogers, Massachusetts, proposes to authorize such sums as may be necessary to provide additional hospital and outpatient dispensary facilities for persons entitled to hospitalization in Veterans' Administration facilities.

MEDICAL ECONOMIC ABSTRACTS

HEALTH PLAN IN HOUSING PROJECT APPROVED

The comitia minima of the Medical Society of the County of New York has adopted a plan to provide four thousand four hundred tenants of the East River Housing Project, 446 East 104th Street, with the services of physicians at low cost, the New York Times reported, November 14. The plan calls for a two year experiment with voluntary cooperation of residents in East River houses. Twenty-five cents a month would be charged for single persons, 50 cents for a married couple, 75 cents for a couple with one child and \$1 a month for a family of four or more. Subscribers would receive the unlimited services of a general practitioner, one resident physician being assigned for every two hundred and fifty families, or one thousand persons. Subscribers would have a free choice of any resident physician. The resident physicians would be selected by a supervising medical board of prominent physicians who are senior members of the staff of the nearest hospital. Resident practitioners would not accept private patients outside the housing area. The New York Foundation, a private fund, will

assume all overhead expenses and guarantee each physician a minimum income of \$1,500, but resident physicians caring for the full quota of two hundred and fifty families, or one thousand persons, would earn \$3,000 a year. A board, consisting of two senior members of the medical board of a neighborhood hospital and two physicians appointed by the county medical society, would act in a supervising capacity and the project would be governed by the East River Medical Council, consisting of four members of the supervising medical board and two representatives of the tenants' association. Persons with catastrophic illnesses would not be taken care of by the plan but would continue to be referred to the wards of the local hospitals. Maternity care would be provided in hospitals as before, but antepartum and postpartum care would be provided by the resident physicians. To make physicians eligible to reside in a low cost housing project, the United States and city housing authorities would authorize one physician to reside on the project for every two hundred and fifty families. The project is similar to the plan placed in operation in 1940 for the tenants of the Vladeck Houses in the Corlears Hook section of New York City by the Medical Society of the County of New York.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2283.

CALIFORNIA

Annual Surgical Meeting.—The Los Angeles Surgical Society held its twenty-fifth annual meeting, December 13. The guest speakers were Drs. Dallas B. Phemister, Chicago, and Stuart W. Harrington, Rochester, Minn. Dr. Phemister spoke on "Massive Resection and Transplantation for Selected Cases of Bone Sarcoma" and "Interruption of the Circulation of Bone and Its Surgical Significance" and Dr. Harrington discussed "Diagnosis and Surgical Treatment of Carcinoma of the Breast" and "Diagnosis and Surgical Treatment of Constrictive Pericarditis." Dr. James F. Percy, Los Angeles, was among the many local physicians on the program, speaking on "Surgery of Advanced Cancer of the Cavities of the Skull."

Annual Graduate Assembly.—The eighth annual postgraduate assembly of the Alumni Association of the College of Medical Evangelists was held at the White Memorial Hospital, Los Angeles, December 7. The speakers were:

- Dr. Harold L. Thompson, Los Angeles, Gastroscopy.
- Dr. Paul M. Hamilton, San Marino, Recent Advances in the Therapy of Communicable Diseases.
- Dr. Thomas Addis, San Francisco, Diagnosis and Treatment of Nephritis in Group Practice.
- Dr. Maximilian E. Obermayer, Los Angeles, Treatment of Pruritus.
- Dr. Charles P. L. Mathe, San Francisco, Urinary Calculi—Management by the General Practitioner.
- Dr. Erle Henriksen, Los Angeles, Sterility.
- Dr. Robert A. Scarborough, San Francisco, Carcinoma of the Rectum.
- Dr. Ben K. Parks, Long Beach, Otitis Media Complications Even with Chemotherapy.
- Dr. Roy E. Thomas, Los Angeles, Atypical Pneumonia.
- Dr. Douglas G. Campbell, San Francisco, Neurotic Personalities in General Practice.
- Dr. Hans Lissner, San Francisco, Indications for and Modes of Administering Testosterone Compounds in the Male.
- Dr. Rodney F. Atsatt, Santa Barbara, Physical Therapy in Care of Fractures.
- Dr. Leo Eloesser, San Francisco, Compound Fractures in War Time.
- Dr. Joseph Brennemann, Los Angeles, Clinical Significance of Abdominal Pain in Children.
- Dr. Walter A. Bayley, Los Angeles, Diagnosis and Treatment of Acute Intestinal Obstruction.
- Dr. Rupert B. Raney, Los Angeles, Surgical Treatment of Intestinal Obstruction.
- Dr. Percival A. Gray Jr., Santa Barbara, Office Management of the Diabetic Patient.
- Dr. William A. Boyce, Los Angeles, The Cross-Eyed Child's Problem.

ILLINOIS

Public Health Advisers.—The governor recently appointed the following to the board of public health advisers in the state department of health: Drs. Walter D. Stevenson, Quincy, Raymond W. McNealy, James H. Hutton and Robert S. Berghoff, chairman, all of Chicago. Dr. Clifford U. Collins, Peoria, was reappointed to the board, which serves in an advisory capacity to the state director of public health.

Chicago

New Koch Laboratory at Armour Laboratories.—Fred C. Koch, Ph.D., Frank P. Hixon distinguished service professor emeritus of biochemistry and recently retired as chairman of the department of biochemistry at the University of Chicago, will continue his researches in the field of endocrines at the Armour Laboratories, it is announced. A newly completed laboratory has been designated the F. C. Koch Laboratory and set up for his use in the chemical research department of the Armour Laboratories.

Research Fellowships at Illinois.—The Graduate School of the University of Illinois has established four research fellowships to be awarded for one year in medicine and dentistry at a stipend of \$1,200 per calendar year, with one month's vacation. Fellows are eligible for reappointment in competition with new applicants. Candidates must have completed a training of not less than eight years beyond high school graduation. Candidates should indicate the field of research in which they are interested and submit complete transcripts of their scholastic credits, together with the names of three former science teachers

as references. The fellowship year begins on September 1. Application blanks may be secured from the Secretary of the Committee on Graduate Work in Medicine, 1853 West Polk Street.

INDIANA

Malaria Control Program.—The state board of health is carrying out a malaria control program in defense industries located in widely separated areas with the assistance of a \$90,000 appropriation by the WPA. The work is now in operation at Fort Benjamin Harrison, the Kingsbury Ordnance Works, near LaPorte, the Jeffersonville United States Quartermaster Depot, the Indiana Ordnance Works and Hoosier Ordnance Plant at Charlestown, the Jefferson Proving Ground near Madison and the army air base near Fort Wayne. In 1938 more than 1,000 cases of malaria were reported at Terre Haute, and in 1939 an outbreak occurred in a lumber camp in Lake County.

IOWA

Outbreak of Undulant Fever.—Up to November 13, sixty-three persons in Marcus, Cherokee County, had been found with positive reactions for brucellosis following an investigation of an outbreak in September involving thirteen persons. In the initial outbreak all the patients gave the history of using dairy products from a producer who distributed raw milk. Agglutination tests on dairy cows led to the discovery of three reactors and one suspicious reactor. The porcine strain of organism, *Brucella suis*, was isolated from milk specimens taken from two reactors. Blood cultures from some of the patients with undulant fever yielded the same organism. New cases subsequently reported were verified by positive agglutination reactions, and in addition twelve persons were found to have positive reactions in diagnostic dilution during a special survey among school children in public and parochial schools. Marcus has a population of 1,206.

LOUISIANA

Industrial Hygiene Section.—The Louisiana State Department of Health will establish an industrial hygiene section in its division of preventive medicine, beginning the first of the year. The U. S. Public Health Service will lend the new section personnel and equipment, according to *Industrial Hygiene*.

The Chaillé Oration.—The sixteenth annual oration in memory of Dr. Stanford Emerson Chaillé was delivered before the Orleans Parish Medical Society, New Orleans, December 2, by Dr. Roy R. Kracke, professor of pathology and bacteriology and chairman of the department, Emory University School of Medicine, Atlanta. His subject was the dangers of self medication with particular reference to analgesic drugs and their effect on the cellular constituents of the blood.

MARYLAND

Physical Examinations of the School Child.—Children entering kindergarten and the first grade of school in the Eastern Health District of the Baltimore health department are being given physical examinations this year in accordance with a new plan. School number 27 was selected for the experimental project, with the examinations being made by the family physician. New pupils whose families have no private physician or who cannot afford one will receive a complete examination by the school physician. Efforts are made to have the parents present during the examination. Pupils selected for reexamination will be those who show physical defects or health problems. The city health department reported in November that almost one half of the new pupils had been taken to family physicians who, in turn, had submitted forty-two reports on their examinations.

MASSACHUSETTS

Personal.—The Louis E. Kirstein Fellowship at Harvard Medical School, Boston, was recently awarded to Dr. Sidney Cohen, assistant in medicine at the school. Dr. Cohen graduated at Harvard in 1937.

Society News.—Dr. Nathan Finkelstein, Pittsfield, discussed "Renal Tuberculosis" before the Northern Berkshire Medical Society, November 6.—Dr. Augustus Thorndike Jr., Boston, discussed "Effects of Physical Therapy on Athletic Injuries" before the New England Society of Physical Medicine in Boston, October 22.—A special meeting of the Boston Health League was addressed, December 5, by Dr. Harold C. Stuart on "Nutrition in Occupied France."—Dr. Henry E. Sigerist, Baltimore, discussed "The Practice of Medicine in Historical Perspective" before the Greater Boston Medical Society,

December 2.—The Worcester District Medical Society was addressed, December 10, in Worcester, among others, by Drs. Edmund J. Croce, Worcester, on "Prothrombin Deficiency in Hemorrhage" and Edward Budnitz, Worcester, "Prophylactic Use of Sulfapyridine in Patients Susceptible to Subacute Bacterial Endocarditis Following Dental Surgery." Dr. Arthur H. Ruggles, Providence, R. I., discussed "The Problem Child of the 'Teen' Age" for the society in November.

MICHIGAN

The Max Ballin Lectures.—The Dr. Max Ballin Lectures, sponsored by the North End Clinic, Detroit, were delivered, November 26, by Drs. Mandred W. Comfort, Rochester, Minn., on "Disturbances of Physiologic Function in Pancreatitis and Their Recognition," and Robert Elman, associate professor of clinical surgery, Washington University School of Medicine, St. Louis, on "Surgical Aspects of Acute Pancreatitis."

Hospital Day.—Woman's Hospital, Detroit, observed "hospital day," December 3, with a special program: Drs. Charles F. McKhann, Ann Arbor, spoke on "Antenatal and Postnatal Influences on Physical and Mental Development of Infants"; Norman R. Kretzschmar, Ann Arbor, "Intrauterine Oxygenic Exchange"; Willis D. Gatch, Indianapolis, "So-Called Toxemias of Burns, Peritonitis and Bowel Obstruction," and William A. Scott, Toronto, some of the difficulties of gynecologic diagnosis. Preston W. Slosson, Ph.D., Ann Arbor, gave a talk at the banquet entitled "Europe's Extremity as America's Opportunity."

Society News.—Drs. Charles M. Henry addressed the Detroit Physiological Society, Detroit, November 13, on "Peritoneal Fluid in Peptic Ulcers"; Samuel J. Levin, "Absorption of Injected and Orally Administered Pollens," and Robert W. Bates, Ph.D., Difco Laboratories, "Recent Studies on the Pituitary and Growth in Dwarfed Mice." All are from Detroit. —William R. Davis, D.D.S., director of the bureau of public health dentistry of the state department of health, Lansing, was installed as president of the Michigan Public Health Association at its meeting, November 13. He is the first dentist to hold this office. Emilie G. Sargent, R.N., director of the Detroit Visiting Nurse Association, was chosen president-elect.

MINNESOTA

Mayo Memorial Shrine.—A bronze statue of the late Drs. William J. and Charles H. Mayo in their surgical gowns will be the central point of interest of the Mayo Memorial Shrine to be erected in Rochester by residents of the city and Olmsted County, *Minnesota Medicine* announces. It will be placed on a granite base before a granite background in the central open space of an amphitheater, symbolic of operating rooms, it was stated. The shrine, designed by James Earle Fraser, New York sculptor, will be separate from that being planned by the Minnesota Memorial Commission. This commission was appointed by Governor Stassen late in 1940 to study the establishment of a \$250,000 fund for a memorial to the Mayos. State Senator William B. Richardson, Rochester, is chairman of the commission, which is composed of seventeen representative citizens of Minnesota.

NEW JERSEY

Society News.—Dr. Martha M. Eliot, associate chief, U. S. Children's Bureau, Washington, D. C., discussed "Child Health in the Defense Program" before the Essex County Medical Society, Newark, November 13.—Dr. Lewis K. Ferguson, Philadelphia, addressed the Camden County Medical Society, Camden, on "Surgical Therapy in Lesions of the Large Bowel," December 2.

NEW YORK

Anthrax Among Mink—One Human Fatality.—The state department of health reports that 163 of 516 mink maintained on a farm were found dead on September 22. Pathologic and bacteriologic findings, reported by the State Veterinary College, Cornell University, Ithaca, showed that the animals had died of anthrax. The mink were owned by three persons and maintained in three separate units on the same premises. Since September 22 no mink have died and, according to their owners, none have been ill, *Health News* states. The district health officer followed up through local health officers all men who had handled the mink. One man who had skinned 100 of the animals was found on October 2 to have an anthrax lesion on his left middle finger below the nail. Antianthrax serum was administered, but the man died. All the carcasses of the animals were disposed of under the supervision of the state

department of agriculture and markets. Only two of the pelts had been sold. These had been sent to a company in a city elsewhere in the state and were located there through the district health officer.

Instruction in Dermatology.—The Medical Society of the State of New York announces a course on dermatology, arranged by Dr. George M. Mackee, New York, for the Montgomery County Medical Society in Amsterdam. The lecturers, all of New York, are:

- Dr. Frances Pascher, Brooklyn, Modern Conception of Allergy: Its Relation to Allergy, January 6.
- Dr. Laird S. Van Dyck, Diagnosis and Treatment of Common Skin Diseases (exclusive of eczema, drug eruptions, cancer and syphilis), January 13.
- Dr. Royal M. Montgomery, Modern Conception of Eczema with Special Reference to Dermatophytosis, January 20.
- Dr. Elias W. Abramowitz, Drug Eruptions, January 27.
- Dr. John Frank Fraser, Diagnosis and Treatment of Cutaneous Cancer and Precancerous Lesions, February 3.
- Dr. Anthony C. Cipollaro, Cutaneous Tuberculosis and Allied Conditions, February 10.
- Dr. Girsch D. Astrachan, Diagnosis, Cutaneous Manifestations and Clinical Course of Syphilis, February 17.

A monthly series of lectures opened October 23 with a talk by Dr. Alexander A. Weech on "Deficiency Diseases." Dr. Gaylord W. Graves spoke, November 24, on "Preventive Pediatrics and the Periodic Health Examination" and Dr. Charles L. Wood, "Blood Dyscrasias in Infancy and Childhood from the General Practitioner's Viewpoint," December 22. Dr. Katharine G. Dodge will discuss "Rheumatic Fever, Chorea and Heart Disease," January 26; Dr. Harry Bakwin, "Diarrheal Diseases, Acute and Chronic," February 23, and Dr. Philip M. Stimson, "Recent Developments in Communicable Diseases," March 23. This series is a cooperative effort between the state medical society and the state department of health. All the speakers are of New York.

New York City

Care of Aged Physicians.—At the annual session of the state medical society in April, the house of delegates voted to allow voluntary dollar contributions to the Physicians' Home to be added to payments of dues, to assist in the care of aged and infirm physicians. On November 29 the home had received about \$5,000 from this source, it is reported. The Physicians' Home was founded in 1918 and reincorporated in 1936.

New County Bulletin.—The Medical Society of the County of New York plans to publish its own bulletin beginning the first of the year. At that time the *New York Medical Week*, heretofore published by the New York Medical Week, Inc., will cease to act as the official publication of the county society. The new publication will be known as the *Journal of the Medical Society of the County of New York*. The advertising manager's office will be located at 230 West Forty-First Street. All other communications should be sent to the journal at 2 East 103d Street.

Study of Pneumonia Extended.—With the opening on December 1 of a seven months study to include the general experience of physicians in New York County, the city department of health announces an extension of its investigation of pneumonia. Heretofore most of the data available for study have come from hospital records. In the current survey private practitioners have been asked to send in monthly reports, on forms furnished by the department of health, on all the pneumonia cases they treat. Information requested includes complete diagnosis, name of therapeutic agent, dosage and outcome, according to the *New York Medical Week*. The survey, available through Social Security funds, will be under the direction of Dr. Wheelan D. Sutliff, assistant director of the bureau of laboratories division of pneumonia control, city department of health.

New Cancer Hospital.—Ground breaking ceremonies took place, October 27, for the new Nightingale Hospital at 163d Street and Fort Washington Avenue, on land donated to the city by Presbyterian Hospital. The new three hundred and fifteen bed hospital will be devoted to the care and treatment of patients with cancer, to research into causes and methods of therapy and to the education of physicians, medical students and others in every phase of this disease. Columbia University College of Physicians and Surgeons will nominate members of the professional staff of Nightingale Hospital except such appointments as are made under the rules of the Municipal Civil Service Commission. The new hospital will replace the old New York City Cancer Institute Hospital on Welfare Island and the Cancer Clinic at 124 East Fifty-Ninth Street. It is expected that the hospital will be completed in March 1943 at a cost approximating \$2,650,000.

NORTH CAROLINA

Electron Microscope Installed in Research Laboratories.—An electron microscope has been installed and put into operation in the laboratories of the division of experimental surgery of Duke University School of Medicine, Durham. This 1,500 pound machine develops 60,000 volts to magnify an object 25,000 to 100,000 times. It was built by RCA in Camden, N. J.

OHIO

Annual Cardiovascular Institute.—The Cincinnati Heart Council and the Academy of Medicine of Cincinnati held their eighth annual cardiovascular institute, November 18. Local physicians participated in the program of demonstrations, lectures and round table discussions. Dr. Homer F. Swift of the Rockefeller Institute for Medical Research, New York, gave the third in the Alfred Friedlander Memorial Lectures series on "The Nature and Etiology of Rheumatic Fever."

Personal.—Dr. Howard C. Stewart, Cleveland, tuberculosis coordinator for Cuyahoga County for three years and director of the county tuberculosis dispensary since it opened in July 1940, has resigned to rejoin the staff of the Tennessee State Department of Health, effective November 1.—Mr. Delmar R. Serafy, formerly executive secretary of the Columbiana County Public Health League and more recently with the National Tuberculosis Association, New York, has been appointed health education secretary for the Alliance Tuberculosis League and the Stark County Tuberculosis and Health Association.—Dr. Irville S. Rian, Massillon, has been appointed medical superintendent of the Ohio State Sanatorium, Mount Vernon, to succeed Dr. Frank C. Anderson, who resigned to enter private practice.

PENNSYLVANIA

Society News.—Dr. Harold T. Brown, Pittsburgh, discussed "Findings in Pulmonary Tuberculosis" before the Fayette County Medical Society in Union, November 6.—Dr. Herbert T. Kelly, Philadelphia, addressed the Cambria County Medical Society in Johnstown, November 13, on "Nutrition as It Applies to the General Diseases."—Dr. Edward J. Stieglitz, Garrett Park, Md., discussed "Problems of Aging" before the Washington County Medical Society in Washington, December 10.

TENNESSEE

Personal.—Dr. Kendall B. Corbin, associate professor of anatomy, histology and embryology at the University of Tennessee College of Medicine, Memphis, has been appointed chief of the division of anatomy, histology and embryology and acting head of the department of anatomy to succeed the late Dr. August H. Wittenborg, who also served as professor of anatomy at the school.

Society News.—Dr. August H. Lancaster, Knoxville, discussed "Congenital Syphilis" before the Knox County Medical Society, December 7. Dr. Henry C. Long, Knoxville, will speak before the society, December 30, on diabetes.—The Shelby County Medical Society devoted its meeting, November 4, to a symposium on the use and abuse of drugs. The speakers were Drs. Arthur P. Richardson, James M. Betha, James M. Brockman, Conley H. Sanford and Neuton S. Stern. All are from Memphis.—Dr. Murray B. Davis addressed the Nashville Academy of Medicine and Davidson County Medical Society in Nashville recently on "Appendicitis in Children."

Changes in Health Officers.—Dr. Derric C. Parmenter, Tupelo, Miss., has succeeded Dr. Thomas L. Harvey as head of the Dyer County health department, Dyersburg.—Dr. Raymond Mel Perry, Pasco, Wash., was recently appointed director of the Sevier County department of health, succeeding Dr. Lamar A. Byers, Sevierville, who is studying at Johns Hopkins University.—Dr. William L. Phillips, Centerville, director of the Hickman County health department, has been named registrar of vital statistics for the county.—Dr. Chester A. Hicks, Cochran, formerly with the Georgia State Department of Health, has been placed in charge of the Carter-Unicoi-Johnson counties health unit, Elizabethton.

TEXAS

In Memory of Dr. Bodansky.—A bronze plaque has been hung in the main building of the University of Texas School of Medicine, Galveston, in memory of the late Dr. Meyer Bodansky, who at the time of his death in June was professor of pathologic chemistry at the university. He had been a member of the faculty since 1919.

State Owned Cancer Hospital.—Recently enacted legislation provides an appropriation of \$500,000 to construct a state cancer hospital. It is expected that the hospital will be at Galveston and operated in conjunction with the University of Texas School of Medicine, with Dr. John W. Spies, dean, in charge. The bill as passed had the endorsement of the state medical association, the state cancer committee, the state medical college, the Women's Field Army of the American Society for the Control of Cancer and the Federation of Women's Clubs.

WASHINGTON

Personal.—Dr. Charles E. Bender, formerly of Fostoria, Ohio, has been made assistant director of the student health service of the University of Washington, Seattle.

Society News.—The King County Medical Society devoted its meeting, November 3, in Seattle to a discussion of anesthesia; speakers were Drs. Dorthie Mae Ness Hopper, William A. Millington, Charles E. MacMahon and Quentin L. Wood. All are from Seattle.—Dr. Edwin A. Nixon, Seattle, discussed "Ligation and Injection Treatment of Varicose Veins" before the Spokane County Medical Society, November 13, in Spokane.

GENERAL

Postgraduate Assembly for Negro Physicians.—The sixth annual postgraduate assembly for Negro physicians will be held at Prairie View State Normal and Industrial College, Prairie View, Texas, March 2-5. The program will include lectures and clinics in tuberculosis, syphilis, heart disease, pediatrics and obstetrics by white and Negro physicians. There will be no registration fee, and any Negro physician licensed to practice medicine in the United States is eligible to attend. The assembly is sponsored by the Texas Tuberculosis Association, the Texas State Department of Health, the Lone Star State Medical, Dental and Pharmaceutical Association, the Prairie View state college, the Hogg Memorial Foundation of the University of Texas and the National Tuberculosis Association.

Foundation Benefits from Will of Founder.—Simon Guggenheim, at one time U. S. Senator from Colorado, who died, November 2, bequeathed the bulk of his estate to the John Simon Guggenheim Memorial Foundation, which he created in 1925 in memory of his son. After certain bequests to persons and institutions have been fulfilled, the foundation receives the residue of the estate and remainder and contingent interest in all the established trusts. The foundation was created to "promote the advancement and diffusion of knowledge and understanding and the appreciation of beauty." Since its establishment it has fostered research in the medical sciences through the award of fellowships. In 1941 a group of twenty fellowships was available for Latin American scholars for study in the United States, nine of which were in medicine and related fields.

Foundation for Eugenic Alleviation of Sterility.—Expanded activities of the National Research Foundation for Eugenic Alleviation of Sterility, Inc., Nesconset, N. Y., have been announced, which include the construction of new quarters, now nearing completion, and the publication of a year book. Lectures delivered during 1941 through the Society for Education in Heredity and Eugenics, under the auspices of the foundation, will be included in the year book. The National Research Foundation for Eugenic Alleviation of Sterility was organized in 1925 and incorporated in 1940. It aims "to reduce sterility in those eugenically sound; to that end to conduct research and to give suitable medical aid, to further education; to publish results and to initiate suitable legislation." Dr. Frances I. Seymour, New York, is medical director of the foundation.

Society News.—Dr. William L. Mann, Corpus Christi, Texas, was chosen president-elect of the Association of Military Surgeons of the United States at its annual meeting, November 1, and Dr. James A. Mattison, Glendora, Calif., was installed as president. Col. James M. Phalen, U. S. Army, retired, Army Medical Museum, Washington, D. C., is the secretary. The next annual session will be held at San Antonio on Nov. 4-7, 1942.—Dr. Harvey F. Garrison, Jackson, Miss., was named president-elect of the Southern Medical Association at the recent annual meeting in St. Louis. The 1942 meeting will be in Richmond, Va.—The American Federation for Clinical Research will hold its annual meeting in Minneapolis, April 20-21, 1942. Dr. Thomas M. Durant, 3401 North Broad Street, Philadelphia, is the secretary.—Dr. Augustus C. Shipp,

Little Rock, was elected president of the Southern Tuberculosis Conference at the recent meeting in Asheville, N C. Bernice Wright, New Orleans, is vice president and J P Kranz, Nashville, Tenn., secretary treasurer.—The annual convention of Phi Lambda Kappa Medical Fraternity will be held in Philadelphia, December 29-January 1, additional details may be obtained from Dr Benjamin B Rittenberg, chairman of the convention committee, 5400 Arlington Street, Philadelphia.

Comparative Cost Estimated in Microfilm Service and Book Lending.—Atherton Seidell, Medicofilm Service, Army Medical Library, has published a report on the comparative costs of loan service and of microfilm copying in libraries. His analysis of the Medicofilm Service showed that in groups of one hundred orders the total expenditure for materials and work at the wage rate of \$1 an hour was \$17.25, or 17½ cents per microfilm. This included the handling of the books, the verification of the film copies and the mailing, but not the time required for keeping the accounts and collecting for the work done. Actual computations of personnel work hours and the time used in the handling of the 13,607 books lent on an annual average for the five year period 1936-1940 showed this cost to be appreciably higher than that of making and sending out microfilm copies. Mr Seidell stated that from the standpoint of the borrower it is evident that those who have not yet become accustomed to using microfilms will object to receiving one instead of the book itself. Others will appreciate being able to keep the microfilm copy. The report states that from the standpoint of library operation, microfilm service has the advantages of permitting the collections to remain intact for their more uninterrupted use as well as reducing wear and tear of the books. A small charge for the microfilms would probably be sufficient to keep the expenses within the allotments for this feature of library service, making it possible for many reference libraries to extend their scope, it was stated. The report also pointed out that the lessened cost of rebinding books due to wear and tear in transit through the mails represents an important factor in estimating savings made by the wide use of microfilm.

Academy of Orthopaedic Surgeons.—The tenth annual convention of the American Academy of Orthopaedic Surgeons will be held at the Chalfonte-Haddon Hall Hotel, Atlantic City, N J, January 11-15. Papers to be presented will include:

Dr Edwin D Weinberg, Baltimore. Two Cases of Late Rupture of the Extensor Pollicis Longus Tendon Following Colles's Fracture

Dr William A Rogers, Boston. Treatment of Fracture and Dislocation of the Cervical Spine

Drs Frederic C Bost and Verne T. Inman, San Francisco. Pathology of Recurrent Dislocation of the Shoulder, Report of Brinkhart's Operative Procedure

Drs William T Green and Sidney Farber, Boston. Eosinophilic or Solitary Granuloma—Is It a New Disease?

Dr Robert L Carroll, Los Angeles. Rate and Amount of Increase in Muscle Strength Following Infantile Paralysis

Dr Mather Cleveland, New York. A Study of Gross and Microscopic Lesions in Tuberculosis of the Spine

Dr William Allan, Charlotte, N C, Prevention of the Hereditary Crippling Diseases

Dr Pedro Toledo Havana, Cuba, What Is Actually the Best Treatment of Acute Osteomyelitis

Drs Philip Lewin and Louis Schemin, Chicago, Experimental Osteomyelitis

Dr Stuart A Thomson, Toronto, Canada, Treatment of Club Feet with Dennis Browne Splints

Dr Jura Farill, Mexico City. Extra-Articular Fixation and Bone Grafting of the Fractures of the Hip—Preliminary Report

Drs Ralph K Ghormley and Markham B Coventry, Rochester, Minn., Surgical Treatment of Painful Hips in Adults

Dr Wallace H Cole, St Paul, Further Report on the Kenny Treatment of Infantile Paralysis

There will be other papers and courses on lame back, roentgen therapy, fractures, arthritis, knee joint vitallium mold arthroplasty, bone metabolism surgery of the hand disability evaluation, foot disabilities, scoliosis bone tumors, peri-arthritis of the shoulder, war surgery, club foot and congenital deformities. A motion picture program will be a feature each day of the meeting.

Encephalitis Research in Yakima Valley.—Mosquitoes have been proved one of the transmitting agents responsible for the spread of encephalitis and encephalomyelitis, the U S Department of Agriculture recently announced in reporting on a study carried on in Yakima Valley of Washington by specialists of the bureau of entomology and plant quarantine, staff members of the University of California Medical School, San Francisco, and Washington state and local health authorities. Nearly 10,000 mosquitoes, flies and other biting insects were collected this season and tested for viruses of the two diseases. The work was conducted in the Yakima Valley because 27 human beings and from 40 to 50 unvaccinated horses had encephalitis in that area during the summer of 1940. The insects were identified, frozen and shipped in solidified carbon

dioxide to the San Francisco laboratory of the University of California, where they were divided into "pools" according to family and species, washed, ground and injected into mice. One pool composed of *Culex tarsalis* mosquitoes produced symptoms of St Louis type encephalitis. Another pool of the same kind of mosquitoes produced the western equine encephalitis. The department of agriculture points out that, while it has been previously demonstrated that mosquitoes can transmit the disease under laboratory conditions, this is the first time that mosquitoes collected in the field have been proved to be carrying the disease virus. The particular species found carrying the virus is widespread in states west of the Mississippi. Further investigation aims to determine whether mosquitoes are the only transmitting agents of the disease in human beings, whether the *Culex tarsalis* mosquito is the only type that transmits the disease, whether mosquitoes must be abundant in order to cause the disease and whether mosquitoes harbor the disease between outbreaks. Successful vaccines for horses have been developed and are widely used but vaccination in human beings is not yet practical, it was stated. More than 3,000 cases of human encephalitis with about 9 per cent fatalities were reported this year by the U S Public Health Service.

CORRECTIONS

Izenstein Instead of Eisenstein.—Dr Louis A Izenstein of Springfield, Mass., writes that his name was misspelled in footnote 16 in THE JOURNAL, November 29, page 1847.

Leprosy in Canton.—In the Current Medical Literature department of THE JOURNAL, December 13, in the abstract "Leprosy in Canton," is the statement "Of the 52,000 inhabitants who came to the attention of the author, 84 (16 per cent) were found to show various symptoms of leprosy." The percentage within the parenthesis should have been 0.16.

Calculation of the Addis Count.—According to Dr Ernest B Zeisler of Chicago, the method of calculating the Addis count given in footnote 3 in the article by Pittinos, Craig and DeSanctis in THE JOURNAL, November 29, page 1855, contains an error. The first term in the numerator of the fraction reads "number of squares counted" instead of "number of casts or cells counted." The denominator reads "volume of area counted", it is obvious that the authors mean "volume counted." Dr Zeisler believes the formula could be amended as follows. Count the number of casts or cells, just as in a leukocyte count, in the four largest squares, namely 4 sq mm, and call this *n*. Then the volume counted is 0.4 sq mm. Now the formula for the total number of casts or cells per cubic centimeter in the twelve hour sample is

$$N = \frac{n \times 12 \text{ hour volume} \times 1,000}{0.4 \times 15/0.5}$$

or, briefly,

$$N = 83\frac{1}{3} \times n \times 12 \text{ hour volume}$$

Government Services

New Facilities for Research in Aviation Medicine

A temporary building is now under construction adjacent to the laboratories of the Division of Industrial Hygiene, National Institute of Health, at Bethesda, Md., to house new facilities for research on problems of aviation medicine, according to *Industrial Hygiene*. This building is intended primarily for a new low pressure, low temperature chamber and accessory refrigerating equipment for the purpose of testing apparatus of all kinds used by aircraft personnel, including such items as oxygen equipment and clothing. The new decompression chamber is expected to provide simultaneous rapid lowering of temperature and pressure to simulate ascent from the ground at atmospheric pressure and 70 F temperature to an altitude pressure equivalent to 45,000 feet and a temperature of -70 F. The rapid change of temperature and pressure obtainable will exceed that encountered in ascent by any modern aircraft. The only other installations of this kind now in operation are said to be at the Banting Institute, Toronto, and the other at Wright Field, Dayton, Ohio. In addition to the work on apparatus and equipment for aircraft personnel, studies are being made on the effects of sudden decompression to low pressures, the effects of anoxia and the influence of altitude exposure on visual function, it was stated.

Fitness of Men Examined for the Armed Forces

Medical examination has revealed a high rate of fitness among the men called up for the fighting services; eight out of every ten have been found fit and many more will probably "make the grade" after a few months of army life. A surprisingly high standard has been found in the age group 37 to 40; six out of ten have been found fit. During the past six months one fifth of the men originally placed in grade 3, the lowest category accepted by the services, have been reexamined and found so improved physically as to be posted to fighting units. Formerly they were serving as clerks, orderlies, batmen and store keepers. Instructions have been given that all grade 3 men are to be reexamined after a few months of army life. In grade 2 comparatively few men have been

Physical Standard of British Man Power

40	1	37
	2	20
	3	15

regraded. This grade is composed of men not quite up to the standard needed for fighting and whose condition does not improve with army training. They are, however, capable of strenuous duties.

The authorities have been agreeably surprised by the high standard of fitness of the older men. It was thought that men in their early thirties would show the effect of poor feeding in childhood during the last war and the sedentary lives they had led, but statistics disprove this. The accompanying table shows in percentages the physical standard of Britain's man power. Actual numbers cannot be given. The Germans claim that their men are far healthier than ours, but the fact is that their examination for army service is not so strict as ours.

Postwar Hospital Planning

The calmness with which the country views the most critical struggle in its history is indicated by postwar planning of many things. In the House of Commons the minister of health has announced that as soon as may be after the war the objective of the government will be to ensure that by means of a comprehensive hospital service appropriate treatment shall be readily available to every person in need of it. At present there are two distinct hospital systems—the voluntary and the municipal hospitals. The former are so called because they are supported by the voluntary gifts of the charitable to provide treatment for the poor. The municipal hospitals have grown out of the

infirmaries provided for the same purpose by the authorities. Though now down to date they do not have the same reputation as the voluntary hospitals, to which the medical schools are attached. At present there is no coordination between the two systems. The minister of health said that it is proposed to lay on the major local authorities the duty of securing, in close cooperation with the voluntary agencies engaged in the same field, the provision of a coordinated service by placing on a more regular footing the partnership between the local authorities and voluntary hospitals. To achieve the best results and to avoid wasteful multiplication of accommodation and equipment it will be necessary to design such a service by reference to areas substantially larger than those of the individual local authorities. To avoid overlapping and uneconomical expenditure, the more highly specialized services at the teaching hospitals and other centers will serve the wider areas, and a proper division will be arranged between hospitals in these areas.

As to the financial aspects of the government's proposals, they intend to maintain the principle that in general patients shall be called on to make a reasonable payment toward the cost, whether through contributory schemes or otherwise. As far as any new burden may be thrown on local authorities in providing or maintaining hospital accommodation or in contributing toward the expenditure of voluntary hospitals, the government will make a contribution. Special arrangements for dealing with the teaching hospitals by way of increased educational grants are in contemplation. In present circumstances the arrangements for hospital services must be determined by war time requirements.

In a debate which followed, labor members demanded the abolition of the voluntary hospitals and the provision of a hospital service for every one by the state. But Sir Francis Fremantle, specialist in public health, said that in the voluntary system they had a wonderful service developed with extraordinary inequalities and deficiencies but also with extraordinary results, which had been the basis of our medical and public health work. Prof. A. V. Hill, physiologist, said that a high standard of humanity prevailed in our hospitals compared with foreign countries such as Germany. Neither *laissez faire* nor bureaucracy in themselves would suffice. It was necessary to find the best possible compromise between the two systems in medicine as in other matters. All concerned should refrain from playing politics and work together for the public good. Whatever form it might take, a universal public health service was necessary as regards both prevention and treatment. The world catastrophe through which we are passing will bring about many changes in this country, but probably only such as would have taken place much more slowly without it. Our hospital system is one of them. We prefer evolution to revolution and progress which conserves the past to destroying it. We can be charged with illogicality, but by our sturdy common sense we manage to secure practical results better than those of more logical peoples.

Red Cross Aid to Russia

A special Aid to Russia Fund has been opened by a committee of the British Red Cross, of which Mrs. Churchill, wife of the prime minister, is chairman. Speaking at a meeting of the fund Lord Iliffe, chairman of the executive committee of the Red Cross, said that we were assisting all our allies to the extent to which circumstances and geography permitted, but the help needed by Russia was on an altogether different scale in keeping with the enormous battle front. For this purpose they would aim at raising \$5,000,000 within a reasonable time. Field Marshal Sir Philip Chetwode said that we had already sent over 140 tons of supplies to Russia and 53 cases of surgical outfits. We were in the closest touch with the American Red Cross in its mission to Russia. Lord Nuffield, the automobile magnate, has subscribed £250,000 to the Red Cross Aid to Russia Fund.

New Official Names for Drugs

One of the effects of the war is that we are producing synthetic drugs which formerly were imported from Germany and we are renaming them. The General Medical Council has issued a further list of approved names for drugs already produced or likely to be produced in this country. Amethocaine hydrochloride is the approved name for decicain, menaphthone for 2-methyl-1,4-naphthoquinone (menadione), perthidine hydrochloride for dolantin, soluble phenytoin for epanutin, eptoin, sodium diphenylhydantoinate, solantoin and soluble dilantin, sulfacetamide for albucid.

RIO DE JANEIRO

(From Our Regular Correspondent)

Nov. 18, 1941.

The Work of the Rockefeller Foundation in Brazil

The twenty-fifth anniversary of the beginning of the work of the International Health Board of the Rockefeller Foundation in Brazil has been enthusiastically commemorated. Besides articles in newspapers and in medical magazines, some medical associations have held special meetings to honor that humanitarian institution. The most brilliant of these meetings was one promoted by the oldest medical association of Brazil, the National Academy of Medicine. Under the chairmanship of Prof. Aloysio de Castro of the University of Rio de Janeiro Medical School the academy held a crowded meeting to honor the Rockefeller Foundation in the person of Dr. Fred L. Soper, its representative in Brazil. The principal speaker was Dr. Afranio Peixoto, professor of hygiene at the university, who reviewed the most salient facts in the services rendered by the foundation especially in the fields of medical education, public health nursing, instruction of sanitarians and the investigation and control of yellow fever, malaria and hookworm disease. Two medical commissions were sent to Brazil early in 1916, the first under Major Gen. William C. Gorgas, to study the yellow fever situation, and the second, composed of Drs. Richard M. Pearce, John A. Ferrel and Bailey K. Ashford, to survey the grounds of medical education, hospitals and dispensaries, public health agencies and sanitary progress. In the same year an effective cooperation began with the Brazilian National Department of Health and with the São Paulo University, growing little by little and leading to the great development resulting in the medical and public health institutions and services now in operation. One lasting result of this cooperation is the University of São Paulo School of Medicine, now housed in a magnificent building of many stories and provided with a faculty of distinguished professors. It is a long work begun with the cooperation of Drs. Samuel T. Darling and Wilson G. Smillie, whose services were an honor to American medical science. Today the São Paulo school is one of the best on the American continent, and its department of hygiene is a leading institute of scientific research in the country. In the field of public health too the cooperation of the Rockefeller Foundation was of the greatest value. The work against hookworm disease begun in 1916 and greatly developed since 1920 has led to the creation of many modern county health units. With the cooperation of the foundation in 1922 the first training school for nurses was founded in Rio de Janeiro, and a Nursing Division was started in the department of health of the city with an able body of ten American public health nurses as supervisors. This led to the creation of a few training schools for nurses in several cities of a large country where the professionally trained nurse was completely unknown before. The nursing service of the department of health of Rio de Janeiro is now an efficient and popular modern agency of health. With the help of the International Health Board of the Rockefeller Foundation, the School of Hygiene and Public Health of the Johns Hopkins University lent the services of two able professors, Drs. Allen W. Freeman

and James A. Doull, to start a course of instruction for sanitarians in the medical school of Rio de Janeiro, and the foundation granted fellowships to many Brazilian public health workers, who went to the United States to study at leading American schools and to visit different public health organizations.

With the support of the Rockefeller Foundation a complete survey of the yellow fever situation developed in the discovery of the jungle form of the disease, the disclosure of sylvatic mosquito vectors other than *Aedes aegypti* (as *Hemagogus capricorni* and *Aedes escapularis*), the invention of the viscero-tome as the leading means of postmortem diagnosis of yellow fever and, through the work of the Rockefeller Institute, the creation of an efficient vaccine, now injected into millions of people, thus protected against the sylvatic yellow fever, as the only practical prophylactic resource. Brazil is also indebted to the Rockefeller Foundation for the help in the fight against *Anopheles gambiae*, the worst vector of malaria, imported into Brazil from the west coast of Africa. Some species of anopheles are more susceptible to infection than others; some anopheles mosquitoes will not bite man at all; others will bite man only when other animals are not available. *Anopheles gambiae* of Africa, which had spread through the states of Rio Grande do Norte and Ceara, entering the great air port of Natal, Brazil, has probably the highest infectibility and the greatest preference for man of all Anophelines. This makes that species the most important vector of malaria in man. The intensive campaign against the gambiae conducted by the malaria service of the Brazilian health department with assistance in funds and personnel from the International Health Board of the Rockefeller Foundation is an outstanding example of "species sanitation." The measures concentrated on were those which would prevent the breeding of gambiae. The eradication of the imported *Anopheles gambiae* is a paramount example of what is possible through the use of modern antimalarial technic, available to the Brazilian health authorities through the invaluable cooperation of the Rockefeller specialists.

Professor Peixoto praised the humanitarian work of the Rockefeller Foundation in Brazil and commended Dr. Soper for his ability to win the friendship of Brazilian physicians, thus insuring once more the unity of the Americas.

Second Brazil-American Congress of Surgery

The second Brazil-American Congress of Surgery is meeting in Rio de Janeiro. The president of the congress is Prof. Benedicto Montenegro of the University of São Paulo, and the secretary general is Prof. Alfredo Monteiro of the University of Rio de Janeiro. The program includes as the main themes (1) the surgery of pain syndromes, (2) burns and (3) amputations from the functional point of view. The principal papers have been contributed by Drs. Jayme Poggi, Motta Maia and Barbosa Vianna of Rio de Janeiro, Drs. Mario Ottobri, A. Correia Netto and Edmundo Vasconcellos of São Paulo, Dr. Julio Dietz of Buenos Aires and Dr. Manuel Riveros of Assunción, Paraguay.

Marriages

JOSEPH MCGUIRE, Dallas, Texas, to Miss Doris C. Nelson of Warm Springs, Ga., in Shreveport, La., November 3.

ARCHIBALD MAXWELL EDINGTON, Camp Borden, Ont., Canada, to Miss Marion Lowry of Ottawa, November 8.

SPRAGUE HEMAN GARDINER, Baltimore, to Miss Mary Sherret Biggers in Toledo, Ohio, October 22.

AUBREY LEIGHTON SPARKS to Miss Thetis Stiles Ashley, both of Warren, Ohio, October 6.

JEROME MORTON SPATZ to Miss Freyda Penner, both of Chicago, November 9.

ELI SILBERSCHNEIN to Miss Moscha G. Weiner, both of Brooklyn, July 14.

Deaths

Robert Dawson Rudolf, Toronto, Ont., Canada; University of Edinburgh Faculty of Medicine, Scotland, 1889; F.R.C.P., London, England, 1910; professor emeritus of therapeutics at the University of Toronto Faculty of Medicine; served with the Canadian Army Medical Corps, with the rank of colonel, during the World War; at one time president and fellow of the American Therapeutic Society and of the Royal Society of Edinburgh; member of the Association of American Physicians; author of a textbook entitled "Medical Treatment of Disease"; aged 76; consulting physician to the Hospital for Sick Children and the Toronto General Hospital, where he died, November 2.

John Broadfoot Rae, New York; University of Glasgow Medical Faculty, Scotland, 1895; at one time professor of diseases of the ear at the New York Post-Graduate Medical School; member of the Medical Society of the State of New York, American Laryngological, Rhinological and Otolological Society and the American Otolological Society, Inc.; fellow of the American College of Surgeons; served during the World War; consulting aural surgeon, Manhattan Eye, Ear, Nose and Throat, Union and Riverside hospitals and Bronx Eye and Ear Infirmary; aged 74; died, November 20, in Douglas, Ariz.

Jesse Wright Downey Jr. ⊕ Baltimore; University of Virginia Department of Medicine, Charlottesville, 1905; professor of otology at the University of Maryland School of Medicine and College of Physicians and Surgeons; member of the American Otolological Society, Inc.; on the staffs of the Baltimore Eye and Ear Hospital, University of Maryland Hospital and the Mercy Hospital; consultant, United States Marine Hospital; aged 59; died, November 18, of hypertensive cardiovascular disease.

Robert Randolph Jones Jr. ⊕ Durham, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1928; assistant professor of surgery, Duke University School of Medicine; fellow of the American College of Surgeons; assistant surgeon, Duke Hospital; director of the Duke Tumor Clinic; director of education of the North Carolina Division of the Women's Field Army for the Control of Cancer; aged 39; was shot and killed by a deranged patient, November 18.

John Bruce Harvie ⊕ Troy, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1881; formerly clinical professor of surgery at the Albany (N. Y.) Medical College; fellow of the American College of Surgeons; past president and secretary of the Medical Society of the County of Rensselaer; surgeon, Samaritan and St. Joseph's Maternity hospitals; consulting surgeon, Leonard Hospital; aged 84; died, November 14, of pulmonary edema and arteriosclerosis.

Elmer Marion Hansen ⊕ Lincoln, Neb.; University of Nebraska College of Medicine, Omaha, 1927; member of the Central Association of Obstetricians and Gynecologists; on the staffs of the Lincoln General Hospital and Bryan Memorial Hospital; aged 48; died, November 12, of coronary disease in St. Louis while attending the convention of the Southern Medical Association.

Luther Curtis Ogle, Etowah, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1913; member of the Tennessee State Medical Association; formerly member of the board of education of Etowah and chairman of the county board of education; aged 52; died, November 9, of injuries received in an automobile accident.

Royall Roller Richardson ⊕ Medical Inspector Commander, United States Navy, retired, Los Angeles; University of Virginia Department of Medicine, Charlottesville, 1899; entered the Navy June 3, 1901; retired March 1, 1935 for incapacity resulting from an incident of the service; aged 66; died, October 18.

William John Mulheran, Syracuse, N. Y.; Syracuse University College of Medicine, 1901; member of the Medical Society of the State of New York; on the staff of St. Mary's Maternity Hospital and Infants Asylum; aged 64; on the staff of St. Joseph's Hospital, where he died, November 7, of coronary thrombosis.

Belle Constant Eskridge, Monrovia, Calif.; Hahnemann Medical College and Hospital, Chicago, 1891; Harvey Medical College, Chicago, 1895; fellow of the American College of Surgeons; aged 82; died, November 9, of complications due to a fractured hip received in a fall.

James Allen Rutledge, Ada, Okla.; University of Louisville (Ky.) Medical Department, 1911; member of the Oklahoma State Medical Association; served during the World War; aged 52; died, November 2, of injuries received in an automobile accident.

John M. Clayland, Brooklyn; Medical College of Ohio, Cincinnati, 1884; member of the Medical Society of the State of New York; aged 81; died, November 23, in the Brooklyn Hospital, of subacute bacterial endocarditis.

Gus Bross Young, Des Moines, Iowa; Drake University College of Medicine, Des Moines, 1904; served during the World War; aged 59; died, November 5, at the Iowa Methodist Hospital of carcinoma of the stomach.

William Mathews, Philadelphia; University of Maryland School of Medicine, Baltimore, 1897; on the staff of St. Christopher's Hospital for Children from 1913 to 1930; aged 76; died, November 1, of arteriosclerosis.

Nathan Sherwood Ferris, Snow Hill, Md.; Georgetown University School of Medicine, Washington, D. C., 1910; served during the World War; aged 54; died, November 10, of carcinoma of the stomach.

Charles W. Murphey, Los Angeles; University of Louisville (Ky.) Medical Department, 1879; Medical College of Indiana, Indianapolis, 1882; aged 84; died, November 6, of cerebral hemorrhage.

Warren Lewis Hulse ⊕ Detroit; Eclectic Medical College, Cincinnati, 1914; on the staffs of the Grace Hospital and the Highland Park Hospital; aged 60; died in November of coronary occlusion.

Emil Joe Pulkrabek ⊕ Flatonia, Texas; Baylor University College of Medicine, Dallas, 1932; aged 38; died, November 3, in the Scott and White Hospital, Temple, of acute monocytic leukemia.

Thomas Jefferson McDaniel, Plymouth, Ill.; Rush Medical College, Chicago, 1886; aged 81; died, November 17, in St. Francis Hospital, Macomb, of bronchopneumonia.

Harry Marr Stoodley, Arlington, Mass.; Tufts College Medical School, Boston, 1904; member of the school committee; aged 63; died, November 5, of coronary occlusion.

Julius Abram Bogart ⊕ Forrest City, Ark.; University of Arkansas School of Medicine, Little Rock, 1902; aged 72; died, November 17, of acute pulmonary edema.

George Francis Spencer, Atlantic City, N. J.; Jefferson Medical College of Philadelphia, 1920; aged 51; died, November 13, of atrophic biliary cirrhosis.

Mortimer Harwood Paine, Hanson, Mass.; Tufts College Medical School, Boston, 1909; aged 65; died, October 1, in Brockton of cerebral hemorrhage.

John B. Griffith, Lewistown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 85; died, November 15, of aortic regurgitation.

Edward Windsor Southall, Geneseo, N. Y.; Homeopathic Hospital College, Cleveland, 1879; aged 90; died, November 12, of chronic endocarditis.

Patrick O'Hair, Waverly, Minn.; State University of Iowa College of Medicine, Iowa City, 1880; aged 93; died, November 7, of heart disease.

Howard W. Pownall, Tyrone, Pa.; Jefferson Medical College of Philadelphia, 1879; aged 84; died, November 8, of angina pectoris.

Henry L. Uhler, Marion, Ohio; Jefferson Medical College of Philadelphia, 1883; aged 81; died, November 2, of coronary thrombosis.

Stephen Stevens, Exeter, Pa.; Bennett Medical College, Chicago, 1915; aged 60; died, November 11, of cardiorenal disease.

George Clarendon Shammo, Philadelphia; Baltimore University School of Medicine, 1898; aged 79; died, November 11.

William Clark Stockton, Milwaukee; Jefferson Medical College of Philadelphia, 1901; aged 68; died, October 23.

Herbert Beals, Buffalo; New York Homeopathic Medical College, New York, 1878; aged 86; died, November 18.

William Arthur Mitchner, Wilson, N. C.; Leonard Medical School, Raleigh, 1908; aged 59; died, November 5.

William Bartley Kyle, Athens, Ala.; Medical College of Alabama, Mobile, 1889; aged 78; died in November.

Roy C. Wolcott, Columbus, Ohio; Pulte Medical College, Cincinnati, 1897; aged 68; died, November 8.

Hector Guy, Miami, Fla. (licensed in Quebec in 1901); aged 67; died, November 14.

Bureau of Investigation

SOME MECHANICAL FRAUDS

Government Closes the Mails to Various Schemes

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of *THE JOURNAL*. Following are brief abstracts of some Fraud Orders not dealt with previously:

Albert Thurlow Hunt and his "Spine Relaxer."—Hunt, a Los Angeles osteopath, for some time sold through the mails what he called "Dr. Hunt's New Cervical Spine Relaxer." According to the Post Office memorandum on the case, the device was found to be a halter attached to rope pulleys and an overhead cross bar. It was to be suspended from a screw eye at the top of a door and the user, seated below it, placed the broad strap under his chin and fastened the narrow, adjustable strap under the back of the head, using the straight edge of the buckle. He then grasped the free end of the cord above the head, causing a downward pull strong enough to put all the neck tissues on a vigorous stretch. This treatment was sold "for relief of the functional disorders of head, throat and neck, headache, insomnia, hay fever, nasal catarrh, catarrhal deafness, enlarged tonsils, sinus trouble, pyorrhea, eye troubles, goiter, apoplexy, neck, shoulder and arm neuralgia, and many other distressing conditions are benefited by the improved circulation which the Relaxer produces." The government produced expert medical evidence to show that none of these conditions are curable by any one device but require treatment based on their causes and manifestations. Although Hunt sent the Post Office Department a letter attempting to explain his alleged manipulative system of therapy, he neither appeared at the hearing of the case nor sent any one to represent him. His treatment was found to be a fraudulent scheme to obtain money through the mails, and on Jan. 10, 1940 it was accordingly debarred by a fraud order. Apparently Hunt thereafter used other means than the mails of shipping it, as the Food and Drug Administration at Washington announced on Nov. 28, 1940, that Hunt had been fined \$50 for selling his "Relaxer" in interstate commerce with false and misleading claims on the label.

"Dr." T. B. Shrader and his "Ear Pump."—Shrader, a chiropractor, put out his device from Lincoln and Syracuse, Neb. It consisted of a red rubber suction cup with a soft sponge rubber face containing an opening so that the device might be placed over the ear. It was represented to restore or definitely improve the hearing of any deaf person regardless of the cause or duration of his condition or the failure of any other method; to overcome head noises, earache, dry ears and other "ear ailments" and to produce in all cases the same benefits as those claimed in the testimonials quoted in the sales literature. Neither Shrader nor any representative of his appeared at the hearing, at which the government presented an expert medical witness, a member of the staff of the Surgeon General of the United States. He testified that ear disorders may result from various causes on which a device like the Shrader "pump" would have no effect whatever or, if any, an almost negligible one. Its sale was accordingly declared to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and it was debarred from the mails by a fraud order issued on Oct. 14, 1940. (Shrader's Ear Pump was declared not acceptable by the Council on Physical Therapy of the American Medical Association, as reported in *THE JOURNAL* April 19, 1941, page 1771.)

Surehold Company's Truss.—"The Surehold Truss" was put out from North Quincy, Mass., and Westbrook and Portland, Me., by the Surehold Company, whose manager was a W. I. Kennedy. He is reported to have said that in 1936 he purchased the business from the estate of the original owner (not named), who had started the enterprise some fifty years before in Westbrook. It was found that neither Kennedy nor any one else connected with the business had any medical training. In addition to the device, the concern sold a nostrum "Rupturine" which was represented to relieve "outward irritation and pain." Although the truss was represented as a "cure" for hernia, an expert medical witness testified that it was not essentially different from, or superior to, other kinds of trusses but a simple spring type device commonly used. The Post Office Department declared the sale of it a fraudulent means of obtaining money through the mails, and a fraud order debarring it was issued on June 28, 1940.

George W. Lowe's Sure Hold.—From Los Angeles one George W. Lowe sold through the mails what he called "Lowe's Sure Hold Appliance." This apparently had no connection with the "Surehold" truss dealt with in another paragraph, although from the government's description the two seemed to be similar. It is not surprising, therefore, that an expert medical witness testified that Lowe's device would not cure a hernia or hold it in place, as represented by Lowe in his use of customers' testimonials. It was even shown that in 1 case Lowe sold his appliance to a person who had definitely stated that he desired it for the cure of a hernia the size of a hen's egg. The business was debarred from the mails as a fraud on Oct. 2, 1940.

Oscillatherm.—This was put out by an A. E. Ovist and an O. L. Durham, an electrician and a chiropractor, respectively, trading as the Oscillatherm Company of Los Angeles, with a distributing branch at South Bend, Ind. They represented through the mails that their device when used as directed would safely, painlessly and effectively correct and overcome disorders of the prostate gland, restore that organ to a normal, healthy condition that would make surgical operations on the prostate

unnecessary, and that it was the "best, safest and most effective" means available to the public for the correction of disorders in its field. The Oscillatherm was found to be an electrically operated mechanism to dilate and heat the rectum and massage the prostate. An expert medical witness for the government testified that a person without medical training would be incompetent to determine just what form of prostatic disorder he had, if any, or how to treat it either with the Oscillatherm or by any other method. The testimony further showed that the Oscillatherm would not effectively correct or overcome prostatitis or other prostatic disorders and that its use would be dangerous in cases in which cancer had already set in in causing the patient to delay scientific treatment. On Feb. 5, 1941, the Post Office Department issued a fraud order against the Oscillatherm Company, J. T. Wharton, manager, and their officers and agents. Thereafter, it appears, Ruth H. Welsh, who was said to manage the South Bend agency, sent out mimeographed form letters to former customers of the Oscillatherm Company informing them that their accounts had been assigned to her. On May 31, 1941 the Post Office extended the original fraud order to cover her name, as R. H. Welsh, on the ground that she was aware of the fraud order against the Oscillatherm Company and was deliberately seeking to circumvent and evade the provisions of it in mailing out the circulars mentioned.

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Agnes MacGregor, Inc., Cosmetics.—The Chicago concern that distributes these signed a stipulation with the Federal Trade Commission in February 1941 in which it promised to discontinue the advertising representations that any of the products in question will effectively cleanse enlarged pores, eliminate blackheads, prove a proper treatment for all types of acne, penetrate into the second layer of skin tissue, remove crow's feet, wrinkles or fine lines, nourish the skin, promote the growth of new hair or correct dandruff.

Ambofa Hair Tonic.—This preparation, also known as "Ambofa Cream for Hair," is put out by the Ambofa Products Company, Hastings, Neb. In January 1941 this concern promised the Federal Trade Commission that it would discontinue certain misrepresentations in its advertising of the product. Among these were that it will make hair healthy, restore its natural beauty, color or luster, kill dandruff germs or rid the scalp of dandruff or eczema or prevent hair from falling or fading.

Approved Model Short-Wave Machine.—One Lillian B. Ferentz, trading as Wayne Short Wave Company, Detroit, signed a stipulation regarding this with the Federal Trade Commission in January 1941. In this she agreed to cease representing that her device is a cure or remedy for sciatica, neuritis, lumbago, arthritis, rheumatism or sinus disorders or that it can be used for any purpose, unless it is clearly indicated that it cannot be safely used except under the supervision of a competent physician, and that its use is dangerous in cases of acute inflammatory processes such as nondraining cellulitis, acute arthritis and acute pelvic infection, and under other specified conditions, that the machine produces a "friendly fever" or that a fever can be created by using an electrical short wave machine or that her device is identical with short wave machines used by medical practitioners and hospitals.

Breck Preparations.—These are put out by John H. Breck, Inc., Springfield, Mass., which concern in March 1941 entered into a stipulation with the Federal Trade Commission. In this the company agreed to discontinue certain misrepresentations in the sale of "Breck's Hair Tonic" (designated by the numbers 1A, 1B or 3), "Breck's Lather Oil pH8 Shampoo," "Breck's Special Scalp Cream," "Breck's #1 Hair Cream," "Breck's #2 Hair Cream" and "Breck's Ointment." Among these were that any of the preparations, whether used alone or in combination, differs from other systems of treating hair and scalp troubles or is a competent remedy for eczema of the scalp, psoriasis, alopecia areata, headache, troublesome monthly periods or sick stomach, that any one of them is valuable for adhesions or will bring about a normal condition of the scalp-connective muscles, cause hair to grow, save the old hair, stop or prevent falling hair, atrophy or excessive loss of hair; cause, encourage or quicken the growth of hair, delay its graying, prevent the loss of hair following erysipelas, scarlet fever or other diseases or conditions or aid in restoring the hair in such conditions.

Chasers.—This breath lozenge is put out by Chasers, Inc., of New York. In January 1941 the concern stipulated with the Federal Trade Commission that it would cease advertising its product as "the one effective tablet" which would permanently overcome bad breath due to tobacco, onions, alcohol, garlic, organic derangements, infections and other conditions, do more than temporarily dispel such breath odors or kill or mask all types of unpleasant breath.

Valortone.—This was represented as a herbal treatment that would restore natural luster and loveliness to the hair and achieve results not obtainable from any other preparation. In January 1941 Julius Skinder, Clinton, Ind., operating under the trade names Valortone Herb Company and Lavelle Sales Company, stipulated with the Federal Trade Commission that he would withdraw these advertising misrepresentations and some others, such as that the product would enable users to regain natural color or health of hair or stop dandruff or falling hair.

Correspondence

MARRIAGE IN EPILEPSY AND DIABETES

To the Editor:—In a recent issue of *THE JOURNAL* (October 18, p. 1402) a query regarding the marriage of the epileptic was answered in a manner which I feel demands a protest. The reply ends "At present the only hope of eliminating the disease epilepsy is by birth control among epileptic adults." This reply overlooks two facts: The first is that a person afflicted with epilepsy who marries a normal person may expect one child in forty resulting from the union to suffer from convulsions. The second is that the hope of weeding out a recessive mendelian trait by birth control is so minute as to be negligible.

In interesting contrast is a letter with regard to the marriage of diabetic patients in the next issue (p. 1490). The reply states "If diabetes were to be eliminated by eugenics, not only diabetic patients but all relatives of diabetic patients would have to be sterilized or prevented from marrying." The commentator seems not alarmed to admit that some descendant of the proposed union would be likely to have diabetes. Need one be so alarmed that some descendant of a patient with epilepsy, or of the patient's relatives, will have convulsions? Epilepsy, like diabetes, can now usually be brought under control by proper medication if taken early enough. The medical profession should point the way to a more realistic attitude toward the disease and be willing to examine each case on its individual merits.

TRACY J. PUTNAM, M.D., New York.

SIR WILLIAM WILLCOX

To the Editor:—In *THE JOURNAL* of September 20 your London correspondent reported the death of Sir William Willcox and referred to his skill as a toxicologist, his great experience in forensic medicine, his connection with the Crippen case and his knowledge of chemical pathology, and mentioned his most important writings. He said nothing of his extraordinary and gallant services in the British army in one of its most terrible, fantastic but finally successful campaigns in World War I, that in Mesopotamia, from 1914 until after the official end of the war. The campaign was fought by what was officially the Indian, not the British, army—the Indian army composed of white British and native Indians. It was, of course, a part of the British forces but was really the Indian army, sent from India. The Mesopotamian War was a dreadfully difficult affair, replete with every kind of tragedy.

In the fall of 1914 the British occupied Basra, on the Shatt-al-Arab, the short river at the head of the Persian Gulf, formed by the confluence of the Tigris and the Euphrates. This meant war with Turkey. Conditions were difficult, the climate was atrocious, disease was common and local military actions were many; however, in the summer of 1915 the first advance was made up the Tigris against Baghdad. The army got as far as Ctesiphon but was from there driven back to Kut-el-Amara, where it was caught, besieged and captured. Things were in evil case anyway and made infinitely worse by the high incidence of scurvy and beriberi, which were not brought under control until the arrival of the special army consultants Sir Victor Horsley and Dr. (later Sir) William Willcox. Other diseases were present, heat stroke being the most fatal of all, undoubtedly causing the death of Sir Victor Horsley himself. The value of the work of Sir William during all this trying time cannot be exaggerated.

In 1917, with continued zeal in spite of all possible obstacles, the Indian army advanced a second time and captured Baghdad, where the commanding general, Sir Stanley Maude, shortly afterward died of cholera, which was there endemic. The undoubtedly reason for his death was that he had refused to take the immunizing inoculations against cholera, though he forced all his officers and men to do so; he claimed that a man of his age was immune. A furious controversy arose over his death, the accusation being made that Sir Stanley had been poisoned. Willcox, who had accompanied the troops and attended the general, testified that he was not poisoned; however, it took three months for a special board of inquiry to make up its mind that Sir William was right. Previous to his death General Maude had written of Sir William "I consider his work in improving the health of my forces equal to two divisions [about 30,000 men]. Whatever it costs in work and in money, you must see that the country provides everything that Willcox thinks necessary."

In 1918 more than 50,000 Christian refugees soaked into Mesopotamia from Turkey and Persian Azarbaijan; two thirds were Assyrians and one third Armenians. The Turks and the Kurdish tribes attacked and ravaged them when and where they could. The survivors were finally gathered in a camp on the Diyala River 3 miles from Baquba. The death rate was about 60 a day; typhus fever broke out "but was luckily recognized as such by the ever vigilant Colonel Willcox." To quote from the "Official Medical History:

A large quarantine camp was formed, where all refugees were examined as a preventive measure. Few of the medical officers had seen cases of this fever, and, had the diagnosis not been made by the consulting physician at the time, the disease would probably have spread to the men of the labor corps.

Throughout the whole period of warfare and postwar readjustment a great service was done by the Order of St. John of Jerusalem and the British Red Cross Society, including its Indian branch. In writing of the work of these organizations Colonel Moens mentioned by name only one officer, Colonel William Willcox, "to whose labors the immense and progressive improvement in the health of the troops was so largely due, and by whose never failing help the Red Cross profited beyond all measure."

Throughout those trying years of warfare against men and disease, when death lurked on every side, Sir William carried on steadfastly and courageously while all about him companions died of battle casualties and sickness. The story of the devastating Mesopotamian War is now seldom thought of, but in all the firmament of military medicine the star of Sir William Willcox will shine as brightly as any other.

The notes contained in this letter have been obtained chiefly from the first of two volumes on Mesopotamia: I. "Loyalties—Mesopotamia 1914-1917; II. Mesopotamia 1917-1920: A Clash of Loyalties—A Personal and Historical Record," by Lieut. Col. Sir Arnold Wilson, K.C.I.E., C.S.I., C.M.G., D.S.O., formerly acting civil commissioner in Mesopotamia, political resident in the Persian Gulf, His Majesty's consul-general for Fars, Khuzistan, and so forth (London, Oxford University Press, Humphrey Millford, 1930 and 1931).

It is interesting to note the wide knowledge of this author and cavalry officer, born, brought up and educated in England, transferred to the Indian army and thence to Mesopotamia, who made, in his two fascinating volumes, free use of Latin, Greek, Biblical and other historical quotations. He put at the beginning, alone on one page as an invocation, a poem, "The Band in the Pines," which he found in the *Southern Illustrated News*, printed in 1863 during the U. S. Civil War, referring to the death of General Jeb Stewart's chief of artillery, Major Pelham, a gallant soldier killed at the age of 22.

RICHARD H. MILLER, M.D., Boston.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec. Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

MEDICAL CORPS, UNITED STATES NAVY

Examination. Assistant Surgeon with the permanent rank of Lieutenant (junior grade) and Acting Assistant Surgeon with the probationary rank of Lieutenant (junior grade), Jan. 5-9. Examination will be held at the Naval Hospitals at Chelsea, Mass., Newport, R. I., Brooklyn, Philadelphia, Norfolk, Va., Charleston, S. C., Pensacola, Fla., Corpus Christi, Tex., San Diego and Mare Island, Calif., Puget Sound, Wash., Great Lakes, Ill., Pearl Harbor, T. H., and Naval Medical Center, Washington, D. C. Apply Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, December 20, page 2191.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II. Various centers, Feb. 9-11. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written, Part I.* Various centers, March 31. Final is Dec. 31. Sec., Dr. Paul M. Wood, 745 Fifth

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral* April in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: New York, June. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written, Part I.* Group B. Various centers, Jan. 3. *Oral, Part II* Groups A and B Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral and Written* All Groups Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PATHOLOGY: St. Louis, March 30-31. Final date for filing application is Jan. 30. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: *Oral*, Cleveland, May 13, preceding the Region III meeting of the American Academy of Pediatrics. *Written*, Locally, February 14. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF RADIOLOGY: *Oral* All Groups Atlantic City, June 4. Final date for filing application is April 1. Sec., Dr. Byrl R. Kirklin, 102 110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written, Part I* Various centers, March 2. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written*, Various centers, December. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Indiana June Report

The Indiana State Board of Medical Registration and Examination reports the written examination for medical licensure held at Indianapolis, June 17-19, 1941. The examination covered 15 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and twenty candidates were examined, all of whom passed. One physician was licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical Evangelists.....	(1941, 2)		2
University of Southern California School of Medicine.....	(1940)		1

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Governmental Hospital: Liability to Pay Patient.—The Welfare and Institutions Code of California authorizes the board of supervisors of each county to "establish and maintain a county hospital." Pursuant to that authority, the board of supervisors of Siskiyou County maintained a general county hospital in the city of Yreka, Calif. Patients of the hospital who were able to pay were charged for the actual cost of hospitalization; other patients were treated on a full charity or semicharity basis. There were no private general hospitals in Siskiyou County and consequently the county hospital accepted so many full pay patients that it operated at a financial profit. The plaintiff entered this hospital as a full pay patient for the treatment of a minor leg injury. During the course of the treatment, the plaintiff's leg was placed in a bake oven and left in so long that it was seriously burned and had to be amputated. In a subsequent suit against the county, and others, it was contended that the injuries were due to the negligence of certain nurses and doctors employed by the county hospital. The county demurred to the complaint, the trial court sustained the demurrer, and the plaintiff appealed to the district court of appeal, third district, California.

The defendant county contended that it was not liable for the plaintiff's injuries because, in operating the general hospital pursuant to statutory authorization, it was engaged in a governmental function. The plaintiff, however, contended that by making the charges so high that they resulted in the hospital operating at a financial profit, the county had abandoned its governmental function and entered the field of private business and that it was therefore engaged in a proprietary venture and should be liable for negligence to the same extent as a private institution. The district court of appeal said that the purpose of the statute authorizing the operation of county hospitals was to provide for the furnishing of hospitalization and medical care to persons who actually were in need of that care. Furthermore, the court observed, it was customary for county hospitals to accept pay patients so far as their facilities permitted. In Siskiyou County, because of the absence of any other general hospital, all persons requiring hospitalization were unable to get it, regardless of their ability to pay, if they were denied admission to the defendant hospital. Such persons were therefore actually in need of care, said the court, and the county was clearly at liberty to admit them to its hospital. Furthermore, the county had a right to compel each patient to pay as much of the actual cost of hospitalization as he could afford, and the imposition of a charge for services, even though incidentally resulting in a financial profit to the hospital, was not inconsistent with the exercise of a governmental function. *Davie v. Board of Regents*, 66 Cal. App. 693, 227 P. 243 (abstr. J. A. M. A. 84:310 [Jan. 24] 1925). The district court of appeal therefore held that the county, in operating the hospital, was engaged in a governmental function and was not liable for the negligence of its employees. Judgment for the defendant county was accordingly affirmed.—*Calkins v. Newton*, 97 P. (2d) 523 (Calif., 1939).

Workmen's Compensation Acts: Refusal of Employee to Undergo Operation.—The employee injured his right knee and instituted proceedings to obtain compensation under the workmen's compensation act of Louisiana. An award was made, conditioned on the employee's submitting to an operation to correct his disability, to be performed by a surgeon of his own choice. This the employee refused to do and the matter came before the Supreme Court of Louisiana for review.

According to the record in this case, the injury to the employee's right knee consisted of a fractured internal semilunar cartilage which protruded to the medial side of the knee joint, causing a tumor mass or growth at that point. The testimony showed that the operation to relieve this condition would require the opening of the knee joint, making a split in the capsule and

removing the loose or fractured portion of the semilunar cartilage. The employee contended that the lower court erred in holding that his disability could be relieved by a simple, minor and harmless surgical operation unaccompanied by great pain and unattended by serious risk. The employer argued that the refusal of the employee to submit to the tendered operation released the employer from the obligation to continue compensation payments, taking the position that when a simple and harmless operation which will cure the employee's condition is seasonably and duly offered and the employee arbitrarily and unreasonably refuses it, then that tender of the operation released the employer from the obligation of continuing compensation payments. The medical testimony in the case was in conflict as to whether the operation offered was a simple one, unattended by appreciable risk of pain. A physician called by the employer testified that the operation was comparable to an appendectomy or a tonsillectomy; he did not look on it either as a major or as a minor operation. This witness testified that it was little more than a minor operation and a little less than a major operation, something like removing a tumor from the abdomen. Another witness for the employer, an orthopedic surgeon, testified that in the hands of a competent orthopedic surgeon the operation was a simple one. He testified that from 75 to 80 per cent of persons undergoing such an operation recover completely without showing any weakness in the knee as a result of the operative procedure. He estimated the time of recovery from four to eight months and not exceeding one year. Another physician, who "did the medical work" for the employer, testified that the operation was a simple one because it is so common. The employee called only one medical witness, who testified that he would not consider the operation a minor one and seriously doubted whether the employee's knee would be as strong after the operation as it was prior to the injury.

The Supreme Court of Louisiana thought that if the tendered operation was to be regarded in the nature, as to the seriousness thereof, of a tonsillectomy, an appendectomy or an abdominal operation for the removal of a tumor, it certainly could not in the light of the jurisprudence of the state be considered such an operation that the employee's refusal to undergo it would be unreasonable and arbitrary. The court therefore held in effect that the employee was justified in his refusal to submit to the operation and affirmed the award of compensation after eliminating the requirement with respect to the operation.—*Simmons v. Blair*, 194 So. 585 (La., 1940).

Autopsies: Right of Insurance Company to Demand Autopsy After Burial.—The plaintiff insurance company insured the life of the insured under policies which provided, among other things, that in the event of the death of the insured "The Company shall have the right and opportunity to examine the body and to make an autopsy unless prohibited by law." The insured fell down a flight of steps and sustained a multiple fracture of the skull. Death followed within a few minutes. Two days later the decedent's administrator explained the facts surrounding the death to the insurer's agent, informed him that the funeral had been arranged for the afternoon of the following day and suggested that if an autopsy was desired it should be performed before the funeral because the widow would not consent to one after the interment. The agent indicated that an autopsy would not be required and the funeral took place as planned. Two weeks later, the insurance company requested an autopsy; the request was refused and the present suit ensued to establish the right of the insurer to exhumate the body for the purpose of having an autopsy performed. The district court gave judgment for the insurer and the defendants appealed to the U. S. circuit court of appeals, fourth circuit.

The insurer contended that the exact cause of death of the insured was unknown but that there was reason to believe that it was due to the effects of intoxication. Two physicians testifying for the insurer, who had no knowledge of the physical condition of the deceased at the time of the accident and who had never examined him, stated that the insured might have died from coronary occlusion, arterial aneurysm, apoplexy or internal hemorrhage, that the use of alcohol by the insured would increase the likelihood that one of these diseases con-

tributed to his death and that the only way to be sure was by performing an autopsy. The evidence on the question of intoxication showed that the deceased was not inebriated at the time of his fall and that his general habits with respect to the use of intoxicants were "about the same as 90 per cent of the people who visit country clubs." Six physicians testified positively that the cause of death was a cerebral hemorrhage induced by the fracture. One of these, who had examined the insured two or three minutes after the fall and before his death, stated that the conditions present were inconsistent with either a coronary occlusion or an arterial aneurysm.

Some decisions, observed the circuit court of appeals, in construing a provision like that involved in this case have denied the right to an autopsy after burial unless the insurance policy specifically so authorizes, on the ground that "an unnecessary or unreasonable exercise of the right of autopsy entails a course of action that is abhorrent to the sensibilities of surviving relatives and may involve a desecration of the grave." The more modern rule, however, seemed to the court to be to permit an autopsy after burial if (1) it appears that, through no fault of the insurer, it was impracticable to demand and to perform the autopsy before interment and (2) it appears reasonably certain that an examination of the body will reveal something bearing on the rights of the parties which could not otherwise have been discovered.

The district court in this case found that one day only was available to the insurer between the death and the burial and that this was insufficient to permit an investigation. The demand for an autopsy two weeks after the death of the insured was, in the opinion of the lower court, made within a reasonable time. The district court also found that the insurer had reasonable ground to believe that an autopsy might disclose such a contributing cause of death as would relieve it from liability. Opinions may differ, said the circuit court of appeals, as to whether the period which elapsed after the insurer had knowledge of the death gave sufficient time before interment for a decision on the necessity of an autopsy. The appellate court did not consider it necessary to decide this point in view of the fact that the court was of the opinion that the insurer failed to show that it had reasonable ground to believe that death was not purely accidental within the meaning of the policies. All the evidence, the court continued, tended to show that the insured was killed by the fall and there was no evidence whatever to indicate that he was afflicted by any disease at the time of the accident. The insurer had no basis for its assertion, in the opinion of the court, that disease was a contributing cause of the death but only a hope that in the course of the investigation something might be revealed that would relieve it from liability. Under such circumstances, the court thought it would be unreasonable to compel the representatives of the deceased to permit an autopsy, and the judgment of the district court was reversed.—*McCulloch v. Mutual Life Ins. Co. of New York*, 109 F. (2d) 866 (IV. Va., 1940).

Malpractice: Standard of Care and Skill Required of Specialists.—The defendant physicians specialized in diseases of children. On May 25, 1937 a mother, one of the plaintiffs, requested one of the defendants to call at her home to see her 9 month old son. He was unable to go but sent his office associate instead. The boy was found to be suffering from nausea, diarrhea and an inflamed throat. His temperature was 102 F. The condition was diagnosed as a common cold but two days later the boy's condition became much worse, his temperature rose to 104 F. and his breathing became so heavy that it could be heard downstairs. One of the defendants again examined the boy but advised the plaintiffs that their son just needed rest in bed and that hospitalization was not necessary. The next morning, however, the plaintiffs notified the defendants that they were taking their son to the hospital and requested the defendants to meet them there. The child was put immediately into an oxygen tent and subsequently a throat specialist performed an operation on the patient's throat, the nature of which was not disclosed by the record. The patient's condition continued to get worse, however, and he died two days later. Subsequently the plaintiffs, mother and father of the patient, sued the defendant physicians for malpractice. The jury found

for the defendants, the trial court granted a new trial and the defendants appealed to the Supreme Court of Washington.

The trial court instructed the jury that the defendants were required to possess that degree of care and skill usually possessed by specialists engaged in a like practice in the same or similar communities. In other instructions, however, the jury was told that the defendants were to be held only to that degree of care and skill used by physicians generally at the time and in the locality. These instructions were obviously inconsistent. The defendants apparently conceded that a specialist is held to a higher degree of care than a general practitioner, but they contended that such rule applied only to physicians who specialized in the treatment of a particular disease or organ and not to a group specialty, such as pediatrics. The Supreme Court, however, failed to see any reason why physicians who specialize in the treatment of the diseases of children should not be held to the same degree of care that other physicians practicing the same specialty in the same community exercise. Since the instructions to the jury were conflicting, a new trial was proper, the Court said, because it was impossible to determine what effect such inconsistency may have had on the verdict of the jury.

The defendants further contended that the evidence was insufficient to justify the trial court in submitting the case to the jury. Malpractice, said the Supreme Court, need not be established by direct and positive evidence; circumstantial evidence will suffice. In this case there was a clear conflict in the testimony as to what was done. To the defendants' contention that there was no evidence from which the jury could find that the boy would have lived even though he had received prompt treatment, the Supreme Court replied that the plaintiffs were required only to show that the probability that the child would live was greater if he received prompt treatment than if he did not. There was sufficient evidence, in the opinion of the Court, to justify a submission of the case to the jury. The order granting a new trial was therefore affirmed.—*Atkins v. Klein*, 100 P. (2d) 1 (IVash., 1940).

Charitable Hospitals: Liability to Pay Patient.—While the plaintiff, a woman over 70 years of age, was a pay patient in the defendant hospital she fell out of bed and fractured her hip, the fall being attributed to the failure of one of the hospital's nurses to equip the bed with sideboards. The plaintiff subsequently sued the hospital for damages and obtained a judgment in the trial court. On appeal to the district court of appeal, the plaintiff's judgment was affirmed (87 P. (2d) 374; abstr. J. A. M. A. 114:1406 [April 6] 1940) and the defendant appealed to the Supreme Court of California.

The defendant contended that it was a charitable organization, that there was no showing that it had failed to use due care in the selection or retention of its employees and that therefore it was exempt from liability for the torts of those employees. In the opinion of the Supreme Court, however, the more modern, as well as the more logical, view required charitable hospitals to respond in damages for injuries to a paying patient. The judgment for the plaintiff was accordingly affirmed.—*Silva v. Providence Hospital of Oakland*, 97 P. (2d) 798 (Calif., 1939).

COMING MEETINGS

Annual Congress on Industrial Health, Chicago, Jan. 12-13. Dr. C. M. Peterson, 535 North Dearborn St., Chicago, Secretary.
Annual Congress on Medical Education and Licensure, Chicago, Feb. 16-17. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.

American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Diveley, 1103 Grand Ave., Kansas City, Mo., Secretary.

American Orthopsychiatric Association, Detroit, Feb. 19-21. Dr. Norvelle C. LaMar, 149 East 73d St., New York, Secretary.

Pacific Coast Surgical Association, San Francisco and Del Monte, Calif., Feb. 17-20. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Society of American Bacteriologists, Baltimore, Dec. 29-31. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.

Society of Surgeons of New Jersey, Trenton, Jan. 28. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Favism.—Robinson states that in 1939 he encountered 5 cases of apparent Lederer's anemia but questioned the diagnosis when a year later his first 3 patients returned with the same disease. Shortly thereafter another patient was admitted to the hospital with the diagnosis of uremic coma. The history was typical of Lederer's anemia, but the mother mentioned that two days before the child, who was fond of the blossoms and the beans of Vicia fava, had eaten some uncooked beans. This detail brought favism to mind. Further questioning about the first 3 patients revealed that they had fallen ill on both occasions one or two days after eating broad beans. The other 2 patients seen in 1939 could not be traced, but in August 1940 a 12 year old boy and in January 1941 a 7 year old boy were admitted to the hospital with acute hemolytic anemia a day after they had eaten broad beans. Though favism has previously not been known in Palestine it seems probable that in some cases the illness diagnosed as blackwater fever was in reality favism. The pathogenesis of the disease is obscure. It occurs after the ingestion of uncooked or cooked beans and after inhaling the blossom dust. This, and the severe eosinophilia in the blood and the bone marrow, support the allergic theory.

Chemotherapy and Pneumonia.—Greengard and his co-workers point out that the mortality from pneumonia in children less than 1 year old in 1937 and 1938, before chemotherapy was used, was 32 and 31 per cent, respectively. From March 1939 to July 1940, 289 infants with pneumonia were treated. Eighty-nine of the patients were observed in 1939, when an attempt was made to control the experiment by selecting alternate patients for chemotherapy. The temperature became normal much more rapidly in the 46 infants treated with sulfapyridine: it reached normal by the fourth day, while

in the 43 control patients the temperature was not normal until the seventh day. Likewise the average duration of illness and hospitalization of the treated group were distinctly less than that of the control infants. Also, the pneumonia of the patients receiving sulfapyridine usually did not extend to areas of the lung not involved on admission. All the 200 patients treated in 1940 were given sulfapyridine as soon as the diagnosis was made. The gross mortality among these infants was 10 per cent. Further classification shows that among infants from birth to 3 months the mortality in 1937 was 44 per cent, 46 per cent in 1938 and 12 per cent in 1940. Similarly, in the group from 3 to 6 months of age the mortality in 1937 was 26 per cent, in 1938, 40 per cent and in 1940, 16 per cent. For those more than 6 months old the mortality in 1940 was 7 per cent, in 1937 it was 27.5 per cent and for 1938 it was 22 per cent.

Intradermal Immunization.—Blatt and his collaborators gave intradermal injections of diphtheria toxoid to the 228 positive reactors encountered among 945 children from 1 day to 19 years of age. Of the 228 positive reactors, 151 received one or two intradermal injections of 0.1 and/or 0.2 cc. of alum precipitated toxoid and 77 received intradermal injections of 0.1 and then 0.2 cc. of plain unmodified toxoid purchased on the open market. Of the 93 children given 0.1 cc. of alum precipitated toxoid 48 were retested at the end of six weeks and 7 showed positive Schick reactions. Eleven months after immunization 4 of the 7 still had positive Schick reactions. Of the 38 given 0.1 and then 0.2 cc. of alum precipitated toxoid 36 were retested after eleven months and all had negative Schick reactions. Three of the 20 given two 0.2 cc. doses of alum precipitated toxoid showed positive Schick reactions nine months later and 1 child after sixteen months still had a positive reaction. Only 1 of the 77 children given plain toxoid intracutaneously had a positive reaction after nine months. Sixteen months after the last inoculation, 2 of the children had positive Schick reactions. Unmodified toxoid gave rise to less severe local reactions than alum precipitated toxoid. Therefore the preferred method of diphtheria immunization appears to be the intradermal injection three weeks apart of 0.1 and then 0.2 cc. of unmodified toxoid (Ramon's anatoxin). This should be followed by a third injection if the Schick reaction is still positive.

Bilateral Tuberculous Pleural Effusions.—Paine reviews the 45 cases of bilateral tuberculous pleural effusions encountered at the Manitoba Sanatorium during the last twenty years. In none of the patients was pneumothorax present. The author states that the bilateral involvement was not merely an effusion of the two sides but usually a manifestation of a widely disseminated infection in a person who had unusual powers of resistance but in whom all too often multiple foci of disease eventually developed. The prognosis in bilateral tuberculous effusion is distinctly more grave than in unilateral effusion. Aside from its being followed by a higher percentage of pulmonary tuberculosis, organs (besides the lungs) seldom affected in unilateral pleurisy are involved. Furthermore, often several organs become involved. Bilateral effusion is usually a manifestation of hematogenous infection and not infrequently of generalized miliary tuberculosis. This seems to explain why the presence or absence of pulmonary tuberculosis at the onset

of pleurisy has no particular bearing on the subsequent tuberculosis in other organs and why sanatorium treatment apparently does not materially improve the prognosis.

Follow-Up of Tuberculous Patients.—Stephens states that the status of 1,041 tuberculous patients from the home office and field or sales force of the Metropolitan Life Insurance Company three years after their admission to a sanatorium was: Of the men in the minimal stage of the disease 83.8 per cent were able to work as compared with 30.2 per cent in the far advanced stage; of the women 77.6 and 12.7 per cent were able to work. After five and ten years the same results with regard to stage held true. Death from tuberculosis among persons in the minimal stage who were being cured was fairly infrequent even after the tenth year, when more than half of those with far advanced disease had died. The chances of recurrence among 761 ex-patients who completed their cure and were able to return to their work before December 1938 averaged for the men who were cured in the minimal stage 7.3 per cent per year for five years. This is equivalent to saying that 36.5 per cent of this group will have had a recurrence by their fifth anniversary of completion of cure (ability to resume occupation). For the women the average was 3.9 per cent per year, equivalent to 19.5 per cent in five years. The men in the moderately and far advanced stages had an average recurrence rate of 11.2 per cent per year, or 56 per cent in five years, as compared with 6.1 and 30.5 per cent for the women. These high readmission rates were experienced in spite of favorable conditions during the first cure and supervised rehabilitation. On the fifth anniversary of completion of cure 90 per cent of the ex-patients treated originally in the minimal stages of the disease were at work or were able to work, as compared with 75 per cent of those with advanced tuberculosis.

Acacia in Treatment of Nephrotic Syndrome.—Goudsmit and his associates observed the changes of the serum proteins and the colloid osmotic pressure before and after the intravenous injection of acacia in 28 patients with the nephrotic syndrome. After acacia was administered the edema of 20 patients disappeared promptly, 3 patients with edema failed to respond with diuresis and in 5 no edema was present when treatment with acacia was begun. Statistical analysis of the data reveals a lack of correlation between diuretic response and changes of colloid osmotic pressure; for example, in 4 patients in whom a frank decrease of colloid osmotic pressure was observed the diuretic response was just as satisfactory as in 9 in whom the colloid osmotic pressure was definitely increased. The concentration of serum proteins usually diminished after injections of acacia; the average decrease was 22 per cent of the original concentration. The decrease could not be correlated with the amount of acacia given, the resultant concentration of acacia in the serum or the initial concentration of serum proteins. Increases in circulating plasma volume and concomitant dilution of the constituents of the plasma appeared to account adequately for the decrease of serum proteins. The gross changes in colloid osmotic pressure subsequent to treatment with acacia are directly related to the absolute changes of the

concentration of the serum proteins and of the concentration of acacia. In approximately half of the patients the calculated changes were within 6 mm. of the observed values. These changes were unrelated to the therapeutic effect.

Pasteurella Tularensis.—Ransmeier and Schaub discuss the data of 3 patients who died of tularemia and on whom necropsy was performed at the Johns Hopkins Hospital in December of 1937, 1938 and 1939, and data of 2 patients who died at Vanderbilt University Hospital in 1940. *Pasteurella tularensis* was cultured directly on blood-dextrose-cystine agar from the blood of 2 of the first 3 patients during life and from all 3 at necropsy. In addition, the organism was cultured from a pustule on a finger of 1 patient during life and from peritoneal fluid at necropsy and from the lungs of 2 post mortem. From 1 of the 2 other patients *Past. tularensis* was recovered by direct culture and by mouse inoculation from pleural fluid during life and by direct culture from heart blood at necropsy. The organism in the other patient was found on direct culture of the venous blood four days before death, in the pleural fluid three days before death and in the heart blood after death.

Postmortem Diagnosis of Allergic Shock.—Lund and Hunt established, by the passive transfer method, a diagnosis of allergy at the necropsy of a white woman following the injection of guinea pig protein. The patient, a ward maid in a hospital, had volunteered to serve as a control subject in an investigation in which normal and psychopathic persons were given intracutaneous injections of small amounts of guinea pig hemoglobin. At 9:09 a. m. she and many other volunteers received 0.2 cc. of a solution of guinea pig hemoglobin. Within a few minutes she complained of headache, and respiratory distress, wheezing and intense cyanosis set in. One subcutaneous and three intracardiac injections of epinephrine hydrochloride were given without avail. At 9:25 a. m. she was pronounced dead. All the volunteers were interrogated concerning past illnesses and particularly concerning allergy; the woman who died had withheld the information that she had heart disease and asthma. Despite the fact that sensitivity to guinea pig protein is not common and that the dose given was small, the authors felt that the most tenable explanation of their subject's fatal collapse was allergic shock. It seemed highly desirable to demonstrate whether or not there was in her blood a specific reagin to guinea pig hemoglobin. A specific sensitizing agent corresponding with the material injected was found in the blood serum by the technic of passive transfer. Further investigation revealed hereditary hypersensitivity, anaphylactic death of the patient's mother's cousin and asthma and hay fever in her mother. The deceased had no known contact with guinea pigs, indicating that the development of hereditary hypersensitivity does not necessarily require antecedent contact with the specific exciting substance.

Postirradiation Levels of Blood Phosphorus.—Abels and his associates state that the ingestion of subtherapeutic doses of radioactive phosphorus by 5 patients with leukemia was followed by a rapid increase in the concentration in the erythrocytes of the organic acid-soluble phosphorus compounds. Subsequently, an increased concentration in both the erythrocytes and the leukocytes was observed. This was not the case after the ingestion of nonradioactive phosphorus. To establish whether the change was due to the radioactivity of the phosphorus or to some chemical property of this isotope, the entire bodies of patients were irradiated and direct exposure of the cardiac area was resorted to to ascertain the change in organic acid-soluble phosphorus levels which followed. The irradiation of the whole body was administered by a 185 kilovolt machine at a distance of 500 cm. and at a rate of 0.4 r per hour. The cardiac irradiation was administered by a 150 kilovolt machine with 1 mm. of copper filter, at a distance of 60 cm. through a 10 cm. cone. The results, while qualitatively uniform, varied quantitatively from patient to patient, but the one binding characteristic in all patients was that there was a definite alteration of the organic acid-soluble phosphorus levels in the leukocytes, and usually of the erythrocytes, after all types of irradiation. The alterations following the ingestion of the phosphorus and the irradiation are probably due to the radioactivity of the isotope.

Spontaneous Healing in Renal Tuberculosis.—To prove the contention that spontaneous clinical or objective healing may and does occur in patients with early renal tuberculosis, that is before caseation or extensive anatomic changes take place, Beach and Shultz report the histories of 8 such patients who were under their supervision for six to fifteen years. As signs of tuberculosis elsewhere in the body were absent, diagnosis of renal tuberculosis depended on the recovery and identification

of tubercle bacilli from the urine from one or both kidneys. Varying numbers of pus cells and erythrocytes were always present in the urine from the bladder. Urologic study was usually suggested by the discovery of pus in the urine. During the periodic follow-up examinations of these 8 patients the objective findings or subjective symptoms have not recurred, and in their absence the authors feel justified in concluding that the tuberculous renal lesion or lesions from which these persons suffered at first healed spontaneously.

Complications of Cancer of Rectum.—Seaman and Binnig say that, of 111 patients with cancer of the rectum seen at the Westfield State Hospital from December 1937 to April 1, 1941, 68 were available for preoperative and postoperative observation. The ages of the patients ranged from 20 to 79; 41 were men and 27 women. Eighteen of the men had frequency or urgency of urination or burning during urination. Most of the women complained of some degree of frequency. However, it was not attributable to the rectal growth; leukorrhea was believed to be responsible in nearly all of them. A combined abdominoperineal operation of the one stage Miles type was performed in 42, 6 had the two stage Lahey operation, 4 had a Mikulicz procedure, 8 had posterior resection and the others had modifications of these operations. Postoperatively 2 had pronounced stricture of the deep part of the urethra, 4 had perineovesical fistula, 1 had ureterovaginal fistula, most patients had infection of the bladder, 1 had a ureter tied off accidentally during the perineal part of a resection, 3 had hydronephrosis on the right and 3 on the left side, 1 had pyonephrosis, 2 had infected hydronephrosis on the right side, many patients had dysfunction of the bladder (but no complete neurogenic conditions), and sexual potency, if still possessed before surgical intervention, was lost permanently afterward. There were 2 instances of epididymitis. Urologic complications vary in occurrence and severity, and they are more often due to sympathetic or parasympathetic destruction or some degree of trauma, possibly also to infection. Infection, because of the nerve disturbance and the altered position of the base of the bladder, is a common attendant.

Pseudohypertrophic Muscular Dystrophy.—Branch based the following regimen on the five important facts (increase of creatine in the urine, gradual replacement of degenerating muscles by fatty infiltration, decrease or absence of magnesium in the muscle, decrease of myoglobin in the muscle and the tendency to spontaneous arrest as the person affected matures) known about progressive muscular dystrophy: 1. He gave 8 patients estrogen in an effort to influence the creatine-creatinine utilization and excretion. 2. Choline, in the hydrochloric or chloride form, was given in an effort to influence the metabolism and deposition of fat. 3. An abundance of cow's or goat's milk was given in an attempt to enhance the availability of magnesium. 4. Anemia was prevented. 5. Gonadotropic substance was given in an attempt to hasten maturity and enhance the effect of the estrogen. 6. In addition, general setting-up exercises, physical therapy, fresh air and sunshine were provided. The condition of 2 of the 8 patients treated was hopeless, and they were used only to observe the effect of the estrogen. The creatinine excretion was definitely increased after treatment was started and was maintained at normal, with occasional elevations above normal. The other 6 patients were given the regimen in an effort to improve their general condition and arrest the progress of the disease. A noticeable increase in muscular strength was experienced by 3 patients, 2 were improved and at first 1 was slightly improved but had bilateral otitis media and mastoiditis and the end result was a total failure. The author points out that results over three and a half years have been so encouraging that he presents this preliminary report in the hope that other workers will try the regimen and prove or disprove its value.

Supraventricular Tachycardia in Infancy.—Keagy and Magee report that giving acetyl- β -methylcholine chloride subcutaneously terminated five attacks of supraventricular tachycardia in a boy aged 5 months. The optimal dose of the drug was 6 mg. The attack on admission was one of several which had occurred since birth, the first having occurred at 2 months. After the fourth attack in the hospital the patient was given 0.064 Gm. of digitalis twice a day in an effort to prevent further attacks. The dose was subsequently reduced until 0.008 Gm. was given daily. This proved inadequate, and a daily maintenance dose of 0.011 Gm. was decided on; the child has since had no attacks and has progressed well. An electrocardiogram taken three days after digitalis therapy was instituted shows a normal auricular and ventricular mechanism and a heart rate of 120 per minute. Although the authors feel that it is safe to use acetyl- β -methylcholine chloride they suggest that atropine be available if untoward toxic symptoms should arise. They believe that powdered digitalis leaf has been responsible for the absence of paroxysms. They say that to date there has been no substantial evidence suggesting active pathologic cardiac changes and that the diagnosis of congenital heart defect is not justifiable, although it may be suspected, as the patient has congenitally deformed ears and his sister has congenitally webbed toes.

Epidemic of Infectious Encephalitis.—Leake states that the largest encephalitis epidemic on record in North Dakota and bordering states and provinces has just ended. In North Dakota there were 1,080 cases with 96 deaths, an incidence of 167 per hundred thousand and a mortality of 8.9 per cent. The uniformity of symptoms and the spread of the disease throughout the area affected by the epidemic suggested that only one disease, western equine encephalitis (proved by serum-neutralizing tests), was responsible for the epidemic. In determining its spread it was found that the tremendous predominance among working men could be accounted for only by differences in exposure. Since the male population of working age has a greater exposure in the wheat fields than the female population a reservoir or reservoirs other than man or horses was looked for. Cox, Jellison and Hughes found the virus of western equine encephalitis in all animals inoculated in the spleen and the central nervous system with material isolated from the brain and the spleen of a prairie chicken, a bird of the grain fields. This indicates carriage via the blood and blood infectiousness.

Isolation of Western Equine Encephalomyelitis Virus from Prairie Chicken.—Cox and his associates believe that they are the first to report the isolation of the virus of western equine encephalitis from a prairie chicken. At the time that the bird was killed encephalitis was occurring in many human beings in the immediate vicinity of Rugby, N. D., which in fact was one of the chief foci of the epidemic.

Diagnosis of Chronic Enlargement of Leg.—Luke discusses the numerous causes for the development of an enlarged leg and lists them under six headings: congenital hypertrophy, congenital and acquired lymphatic stasis and obstruction, developmental venous retardation, mixed venous and lymphatic partial obstruction, congenital arteriovenous fistulas and miscellaneous causes. As far as he knows, pure venous retardation as a cause of the condition has not been described. This increased size in a previously unaffected leg is not the same as that due to lymphaticovenous obstruction, in which there is also partial lymphatic blockage. A case is presented which demonstrates that venous retardation can of itself cause enlargement of a leg. The patient had no previous disorder of a leg, phlebitis, pregnancy or any severe illness. The enlargement appeared gradually in early adult life, at a time when defective venous valves in the saphenous system usually appear. Edema as a factor in the enlargement can be ruled out by the absence of pitting on pressure and only a slight diminution in size on prolonged elevation of the leg. Signs of a congenital arteriovenous fistula were not present. The diffuse cyanosis of the leg, most severe on standing, indicated venous congestion, and the absence of enlarged superficial veins ruled out incompetence of the saphenous system; however, this may develop later. Roentgen studies corroborated the clinical impression, in that the absence of valves or defective valves in the deep system of the involved leg were revealed allowing complete retrograde flow. This defect is absent in the normal leg. The hypertrophy of the leg probably resulted from the venous retardation and the prolonged activity of an increased venous pressure over a dilated deep venous bed. The extremity has undoubtedly been endowed with congenitally weaker and fewer valves than the normal leg, and the patient's years of activity as a waitress caused complete defectiveness.

Blood Platelet Count and Coagulation Time.—Potts and Pearl determined the coagulation time of the plasma, with and without platelets, of 52 patients after major operations. The coagulation time of whole blood was also studied. Estimations were made before operation and every day or every other day after operation until the patient's discharge. The average preoperative platelet count was 275,000 per cubic millimeter; on the first postoperative day it fell to 260,000 and remained so until the third postoperative day, when it began to rise so that by the fifth day it was 278,000, by the seventh 292,000 and by the tenth 301,000. By the fourteenth day it fell to 289,000 in the 24 patients who remained in the hospital this long. The average coagulation time of plasma with platelets was constantly practically the same as that of whole blood; except for a slight drop on the first postoperative day neither varied much at any time. The average coagulation time of plasma free of platelets was constantly slightly less than that of plasma containing platelets. There was no discernible relationship between the platelet count and the coagulation time. A platelet count of 120,000 was apt to be associated with a coagulation time of five minutes and a count of 400,000 with a coagulation time of ten minutes; the reverse was just as likely. It seems doubtful that the platelet count and coagulation time following major surgical procedures are of any significance in the development of postoperative thrombosis or embolism.

Uterine Contractions of Early Pregnancy.—Murphy recorded with a Lóránd tocograph the uterine contractions of 250 women between the one hundred and tenth and the two hundred and seventy-ninth day of pregnancy. No spontaneous uterine contraction was noticed until the one hundred and sixty-sixth day, and the expulsive force of contraction increased progressively during the remainder of pregnancy. Patients experiencing uterine contractions prior to the thirty-third week of gestation usually had a significantly shorter labor than those without such activity. Measurement of uterine contractions after the thirty-second week of pregnancy was of no value in predicting the type of labor to follow.

Hepatic Insufficiency in Toxic Goiter.—According to Schmidt and his associates, of 207 consecutive patients with goiter subjected to thyroidectomy 113 presented evidence of hepatic insufficiency as measured by the Quick hippuric acid test. In 34 of these patients the hippuric acid excretion was less than 70 per cent of normal. Hepatic insufficiency appeared related more to the duration and intensity of the thyrotoxicosis than to the type of goiter. Patients receiving specific measures directed at correcting hepatic function showed greater improvement and were better operative risks than a control group of patients treated only by conventional measures. Postoperative morbidity and mortality of severely toxic patients with goiter probably can be significantly decreased by therapeutic measures directed at improving hepatic function. The authors have had only 1 of 370 consecutive patients die after thyroidectomy.

Causes for Increased Tuberculosis Mortality in Glasgow—According to Laidlaw and Macfarlane, for five years preceding the outbreak of the present war the incidence of and the mortality from pulmonary tuberculosis tended to stabilize themselves in Glasgow at annual figures of around 1,650 notifications and 960 deaths. During the first year of the war the returns were 1,908 and 1,177, respectively. This increase is being maintained during 1941. The increased incidence has taken place almost entirely between the ages of 15 and 45 in males and 15 and 35 in females. The figures for nonpulmonary tuberculosis for 1939 and 1940 also show a considerable rise in notifications and deaths. The possible reasons for the increased incidence are increased virulence of the tubercle bacillus, malnutrition and deficient diet, tubercle bacilli in milk, examination by military medical boards, exertion or strain of army life, long hours in shelters, overcrowding in factories and longer working hours, strain and curtailed rest. A study of these factors shows that a combination of long hours, overtime, strain and ill spent leisure has produced the rise in the number of cases of tuberculosis. The increase will be maintained while these factors remain unchanged.

*Electroencephalogram in Acute Head Injuries D Williams—p 107
*Electroencephalogram in Chronic Post-Traumatic States D Williams—p 131

Electroencephalogram in Acute Head Injuries.—Williams made electroencephalograms of 74 patients (drawn from a series of 600 patients admitted to a special center for injuries of the head) within twenty days of their injury. The initial electroencephalograms of 42 of the 74 patients were normal, and their subsequent clinical recovery was uneventful. The patients were unselected, and all were members of the army and the Royal Air Force. Their ages ranged from 18 to 60 years. Their injuries varied from simple concussion to severe cerebral laceration with dural penetration and cerebral herniation. Slow waves were invariably present when consciousness was impaired. The degree of abnormality was closely correlated with the clinical state of the patient. In patients with severe injuries the abnormalities persisted for many weeks. The rate of clinical and of electroencephalographic recovery corresponded closely, but there were wide individual variations in the speed of return to normal. In the later stages of recovery the electroencephalogram was sometimes abnormal after the patient had made a complete clinical recovery. Localizing clinical signs corresponded with the area of abnormality seen in the electroencephalogram. An epileptic type of disturbance occurred in the immediate post-traumatic period, but it had no prognostic significance in relation to post-traumatic epilepsy. The author concludes that the electroencephalogram accurately reflects the abnormal cerebral state caused by a recent injury to the head,

that the progressive changes are a direct indication of improvement or deterioration and that in the milder instances of cerebral dysfunction it may demonstrate residual damage after abnormal clinical signs have subsided.

Electroencephalogram in Chronic Post-Traumatic States.—Williams states that the electroencephalograms of the 600 previously mentioned service personnel were taken from a few hours to twelve years after injury. Fifty per cent of the patients had abnormal electroencephalograms. This high percentage persisted for many years after injury. There was a positive correlation between it and the severity of the injury, the persistence of symptoms and dural penetration. Of 87 patients invalided from the services, 67 per cent had an abnormal electroencephalogram. In 207 patients, 55 per cent of whom had abnormal electroencephalograms, the symptoms were thought to be due to organic damage. The electroencephalograms of 37 per cent of 50 constitutionally inferior patients and of 20 per cent of 58 with symptoms due to an exogenous neurosis were abnormal.

Middle Class Diets in Peace and War.—From a study of the records of a dietary survey made in 1935 on 63 men and 63 women of the English middle class Widdowson and Alington found that in 1935 the men ate an average of twice as much sugar and bacon, three times as much meat, butter and jam and five times as much cheese as rationing allowed them in the spring of 1941. In 1935 the women ate less of these foods than the men, but the quantities, with the exception of sugar, exceeded the rationing in the spring of 1941. A survey of the diets of 57 middle class women in the spring of 1941 revealed that much less raw fruit and less unrationed meat, fish and sweets were consumed by the women than in 1935. However, milk, bread, cereal foods, potatoes and vegetables were being consumed in larger amounts in 1941. The 1941 survey showed that a prewar level of calories was maintained by the women by substituting unrationed carbohydrate for rationed fat. Their intake of protein, other than animal protein, and of phosphorus was unchanged, and their calcium and iron intake was high in 1941. The average daily vitamin C intake in 1935 was 57 mg. and in 1941 it was 27 mg. The decrease was due to the unavailability of raw fruit.

- Bilateral Phrenic Exclusion. O. P. Aguilar and C. A. Bancalari.—p. 235.

Hemorrhagic Pleurisy and Hemopneumothorax.—Raimondi and Lerner define those pleural effusions which are red and contain a large number of erythrocytes as hemorrhagic pleurisy. Although the most important causes are cancer and tuberculosis, hemorrhagic pleurisy can be found also in acute rheumatism, typhoid, pneumonia, influenza, syphilis, hepatic cirrhosis, nephritis, malaria, chronic alcoholism and hemorrhagic disorders, such as scurvy, purpura, leukemia and smallpox. The pathologic aspects of hemorrhagic pleurisy are similar to those of serofibrinous pleurisy, with the difference that one frequently encounters abundant proliferation of new vessels and pleural membranes. The increased number of erythrocytes in the effusion is due to such mechanisms as diapedesis and rupture of newly formed capillaries and of fragile walls. The effusion is bright red, but if old it takes on a violet color. Cancer is the cause so frequently that whenever hemorrhagic pleurisy exists it is necessary to employ all diagnostic aids that will eliminate cancer as a possible cause. Hemorrhagic pleurisy can supervene in patients with cancer of the stomach, the uterus, the breast and so on, and it may indicate that metastasis has taken place. When it is the first sign of cancer, two possibilities must be considered: (1) that hemorrhagic pleurisy may mask a tumor which, after the evacuating puncture, can be easily recognized clinically by various forms of roentgen examination and bronchoscopy; (2) that hemorrhagic pleurisy may be symptomatic of primary cancer of the lung or the pleura, in which case the clinical difficulties are great. Tuberculosis is the other frequent cause of hemorrhagic pleurisy. It may be primary or secondary to acute or chronic pulmonary tuberculosis. In order to characterize hemorrhagic pleurisy as tuberculous and primary, the following conditions must be fulfilled: (1) absence of tuberculous lesions, (2) presence of tubercle bacilli and (3) appearance of tuberculous lesions immediately after production of the effusion. On the basis of these conditions primary tuberculous hemorrhagic pleurisy is extremely rare. Secondary tuberculous hemorrhagic pleurisy is more frequent than the primary form. It may occur in acute forms (miliary tuberculosis, caseous tuberculosis) or in chronic forms. When accompanying the acute forms, it is frequently bilateral and characterized by intense dyspnea and a rapidly fatal evolution. When secondary to chronic pulmonary tuberculosis, the development is determined by the pulmonary status. Hemorrhagic pleurisy may supervene after suspension of artificial pneumothorax. If it takes a benign course, the treatment consists in the evacuation of the effusion with or without reinsertion of air. The malignant form, which is less frequent than the benign, is produced when a subpleural tuberculous lesion opens into the pleural cavity. In this condition, thoracoplasty seems to be the only therapy likely to prevent a fatal outcome. Discussing spontaneous hemopneumothorax, the authors show that hemorrhagic pleurisy is customarily not an inflammatory condition but a hemorrhage accompanying spontaneous pneumothorax. Both the tuberculous and the nontuberculous forms of spontaneous hemopneumothorax are rare. They encountered only 3 cases in 94,914 case records.

Roentgenologic Examination of Attendants of Tuberculous Patients.—Raimondi made periodic roentgen examinations of 341 persons who lived in an environment where they were exposed to tubercle bacilli and found that 21 per cent had mild or grave forms of tuberculosis. The majority began with a form of tuberculosis that presented no symptoms or only slight symptoms. The incipient lesions are tractable to treatment; success is often obtained with ambulatory treatment. It is essential to convince persons who live in the environment of

patients with open pulmonary tuberculosis of the necessity of periodic roentgenologic examinations, because, although subjective symptoms may be absent, pulmonary lesions may at times advance unnoticed. Periodic examination will insure diagnosis when the disease is in the incipient phase, so that it will be possible to institute effective treatment. The author calls attention to the relative frequency with which hematogenic forms are encountered in adolescents and young adults who are exposed to infection. On the basis of statistical studies and of several observations the author supposes that exogenous reinfection is of importance in the genesis of the disease.

Tokyo Igakkwai Zassi, Tokyo**55:529-620 (July) 1941. Partial Index**

- *Histopathologic Studies of Diabetic Kidneys with Special Reference to Changes in the Glomeruli. R. Murakami.—p. 529.

Glomerular Pathology in Diabetes.—Murakami made histologic studies of kidneys in 27 cases of diabetes mellitus, including 7 instances of death resulting from acidotic coma, with special reference to the changes demonstrable in the glomeruli. The most striking changes in diabetic kidneys were found to be enlargement of the glomeruli due to both regressive cellular swelling of the basement membrane and progressive hypertrophy and hyperplasia accompanied by hyperemia. Hyalinization, fibrotic union of capsules and fatty and glycogen degeneration of the parenchyma were also noted. All these changes in some instances at least appeared to be reversible, paralleling the clinical course in each case, but parenchymatous degeneration was not clearly demonstrable in cases of acidotic coma or of renal complications. Although the pathologic changes of the diabetic kidney resemble those seen in nephrosclerosis, the two conditions can be cytologically differentiated. The changes may be regarded as a cumulative product which is compensatory to functional disturbances, caused by the stimulating effect of overfunctioning organs and of tissues saturated with the abnormal composition of the urine. The predominance of these changes occurring in the glomeruli and the terminal capillaries may be due to the chief excretory function which these tissues perform, together with the contributory effect of the specialized structure of the glomerular tufts. The appearance of epithelial cells at the end of the Bowman capsule is probably but an extension of the main epithelium. Although there is no direct evidence of any organic relation between this disease and other lipemic diseases, yet the abnormal enlargement of the glomerular tufts may aggravate the lipemic kidney and accentuate the existence of such diseases by epithelial hypertrophy. The diabetic kidney may thus be regarded as representing a case of glyconeuphrosis under the general category of glomerular nephrosis.

Visceral Blood Vessels in Thromboangiitis Obliterans.—Teilmann reports a case of severe thromboangiitis obliterans in a man aged 43 with gangrene of both lower extremities. Necropsy showed, besides the characteristic changes in the arteries of the extremities and of the pelvis, (1) thickening of the intima and obliteration of the peripheral part of the main descending branch of the coronary artery, with corresponding thickening of the intima and more peripherally almost complete obliteration of the afferent arterial branch. This, together with a few similar observations previously published, supports the assumption that in Buerger's disease there is a general disturbance of the arterial system.

The Future of Pediatrics

WILBURT C. DAVISON, M.D.

DURHAM, N. C.

Although pediatrics is one of the oldest of the clinical specialties, dating from Bagellardus, Metlinger, Phaer, Hieronymus, Sainte Marthe and Glisson (1453-1600),¹ it is only in recent years that the growth has been rapid, owing in no small part to a demand on the part of the public for better medical care for the child.² This same demand is leading to more intensive development of child health activities on the part of the state and to the acceptance of the ideas that the health of the child is a responsibility of the government somewhat analogous to the way in which education has been a state responsibility and that, if the American child is entitled to an education, he is entitled to health.³ At present pediatrics, through its own commendable efforts in prevention³ and also for economic reasons, may lose its strictly clinical aspect and become increasingly merged with preventive medicine and public health. In fact, the pediatrician is fast becoming a liaison officer between the public health service and private medicine.⁴

There are four reasons for this trend: (1) the advances in preventive pediatrics, (2) the nature of pediatric practice, (3) the increasing number of pediatricians and (4) the improved pediatric training of general practitioners.

1. The advances in preventive pediatrics, most of them made by pediatricians themselves, have eliminated many of the pediatric problems, so that the need for practicing pediatricians is decreasing. A generation ago the majority of patients were children. Now ill children are in the minority because (a) diphtheria, whooping cough, dysentery and typhoid are becoming rarities, (b) pneumonia, meningitis and dysentery are successfully treated with sulfonamide derivatives, (c) congenital syphilis is reduced through more adequate treatment of pregnant women, (d) infant feeding is simplified⁵ and nutritional knowledge increased, (e) the mortality in children has decreased 66 per cent and (f) the ratio of children to the total population is reduced from 1:3 to 1:4 as the result of the falling birth rate and the increased longevity of adults.⁶ However, the need for continued and improved preventive pediatrics cannot be overemphasized; 75 per cent of the deaths among children are preventable, and it is in this field, as well as in practice, that pediatricians always will be needed. More and better research on the cause, cure and prevention of children's diseases, in addition to greater stress on preventive pediatrics, also is necessary.

2. Pediatrics is essentially general practice limited to the care of children from birth or even before birth to or through adolescence⁷ and therefore pediatricians are in constant competition with other specialists, health and infant welfare agencies and with general practitioners, for "the majority of the children in this country are cared for by general practitioners and not by pediatricians."⁸ Furthermore, the percentage of graduates who are going into general practice apparently is increasing.

3. At present there are 4,205 pediatricians—2,205 full specialists and approximately 2,000 partial specialists—of whom 1,620 have been certified by the American Board of Pediatrics.⁹ It is possible that the opportunity for successful pediatric private practice may be lost because of a supply greater than the demand.² It is doubtful whether the public can support a larger

9. Veeder.² Evans.⁴

number of pediatricians, as half of the babies born each year are in families on relief or with an annual income of less than \$1,000. Fair remuneration to the physician is essential to good care.² As the average age of the practicing pediatrician is approximately forty years and replacements will be slow, graduates of today who wish to care for children may have difficulty as specialists and probably should enter general practice or obtain health department positions, even though this statement may be interpreted as a lamentation of Jeremiah or a tribulation of Job.

4. The improved teaching of pediatrics in the medical schools has enabled many of the present graduates who are going into general practice to have a more practical knowledge of pediatrics than some of the interns in the children's hospitals had a generation ago.² In addition, the increased number of pediatric internships has made postgraduate pediatric training available for general practitioners. Twenty years ago almost all pediatric interns went into pediatric practice, but during the past ten years 40 per cent of those at Duke Hospital have gone into other fields.

In spite of these trends in pediatrics, some practicing pediatricians always will be needed, as the clinical problems of children differ from those of adults.¹⁰ Pediatric teachers and members of state and federal health organizations also are necessary in order to perpetuate and increase the advances made in preventive pediatrics.³ Most of the present American pediatricians are maintaining successful practices, particularly those who emphasize preventive measures and include child guidance, mental

hygiene and adolescent care in their field.¹¹ The small to medium sized cities are the best places in which to practice, as the larger cities are oversupplied with specialists and the small towns can seldom support them. Low fees for prophylactic measures, which are given free by health departments, and agreements with a family to render pediatric services for an annual fee have been helpful, i. e. full service of unlimited office and home visits and immunization for \$60 to \$85, or well baby service of office visits and telephone calls but not home visits for \$35 to \$80.

The problem of pediatric instruction in medical schools has therefore changed; in 1930 it consisted in teaching pediatrics to medical students, most of whom planned to enter some specialty, and the provision of postgraduate training, through internships and residencies, for future pediatricians. Now the latter are decreasing, but a greater need has arisen—the laying of a sound foundation for every student's development in pediatrics, especially in the care of newborn infants, as 40 per cent or more may go into general practice, and short intensive pediatric courses for physicians who have been in general practice for several years. Duke University's answers to these new demands are a heavy pediatric teaching schedule (two hundred and seventy-nine hours), pediatric internships and residencies, obstetric-pediatric internships and weekly obstetric-pediatric postgraduate courses for general practitioners, sponsored by the North Carolina State Board of Health, the U. S. Children's Bureau and the University of North Carolina School of Public Health.

Digests and Reviews

PERSONALITY IN PRACTICE

Abbreviation of an address to the graduating class by Dr. Louis J. Karnosh, of Western Reserve University School of Medicine, Cleveland, June 11, 1941, published in the Clinical Bulletin of that school in September.

What you have achieved today places you in a unique category which you will more keenly appreciate through experience. An analysis of the bibliographic indexes published in this country reveals that the probabilities of your becoming distinguished by virtue of being a physician are five times as good as they are for a lay or nonprofessional person. This implies great expectations, but by the same token it also implies that a stark failure among you is all the more glaring.

Despite the fact that you are now marked men and women, the distinction you are acquiring today is in a sense an artefact. The class of 1941 remains as a vertical sampling of normal human nature. The degree of Doctor of Medicine does not restratify, neither does it stereotype your individual personalities. The same proclivities and dispositions which were in part displayed in your freshman aptitude test, which were exposed as the unguarded mannerisms of the classroom and which more freely exude from you in the informal atmosphere of the fraternity house or dormitory, will still guide and propel you in definite directions. These make for the prime differences which exist among physicians—no more, no less than they do among stock brokers or laborers or members of the Thursday lunch club.

A SORT OF INTELLECTUAL FANATICISM

I should like to speak of virtues which, because they are virtues, may be allowed to grow on one to the point of becoming unbecoming and disabling. I shall speak first of those among you who are the factualists and precisionists in medicine. You represent the heart of medicine, without which there can be no supporting frame or structure. Your ultimate criterion is the test tube, your senses are tuned to a cold objectivity, and the ailing body is a synthetic mass of malfunctioning organs. In your tower of crisp calculations you make invaluable deductions, but your precisionism is sometimes acquired at the cost of an appropriate sense of humor. Patient with all other facts in medicine, you may find yourself impatient with the fact that the ailing person stubbornly insists on being emotional and sentimental. You can't count on him as you can on the Bence Jones protein reaction. Cold objectivity has its place in the ivory tower, but at the bedside it may become a piece of clumsy grotesqueness. The distinction between a human being and a guinea pig becomes wider and wider the more remote in recollection become your experiments in the laboratories of the medical school.

The pursuit of a specific item by a method of precision and the feverish desire to apply it to the humanities may often become a sort of intellectual fanaticism. This is well demonstrated in the case of Bischoff, one of the leading anatomists of Europe, who thrived some seventy years ago. He carefully measured brain weights, and after many years' accumulation of much data he observed that the average weight of man's brain was 1,350 Gm., that of a woman only 1,250 Gm. This at once, he argued, was infallible proof of the mental superiority of men over women. Throughout his life he defended this hypothesis with the conviction of a zealot. Being the true scientist, he specified in his will that his own brain be added to his impressive collection. The postmortem examination elicited the interesting fact that his own brain weighed only 1,245 Gm.

It is well to develop the hard sheen of scientific exactness in the laboratory; it is just as important that in the clinic and the sickroom this surface be polished to a softened and velvety patina. The addict to exactness must be frequently reminded that in the art of medicine a sick patient who gets well without a diagnosis is better off than a dead one with a complete pathologic report.

Second, there is the classmate among you with the encyclopedic mind. It is often announced by a jeweled display athwart the vest buttons. You are hailed as a ready reference system which forestalls the need of frequent visits to

the library—in short, a walking bibliography. Of you we can never be too proud, provided all your other sensitivities are equally astute, especially the nerve endings in your finger tips, and provided your lingual muscles are not over-exercised at the expense of those in the forearm and hand. Yet, if you are so blessed, your virtues are tempered by certain unfavorable drifts. Pedantry and peripatetism are your trends, which is another way of saying that at times you may become an awful bore.

There is a temptation on the part of the encyclopedic medical mind to feed too much on the rarities and unique syndromes. It is above the common cold and simple constipation. It should live on simpler fare. It is too fond of wandering into obscure entities and diverticula, where it loses itself in a maze of didactics. This often exposes it to ideas and medical vogues which are new but not true; a reputation built up by exploiting them may go up with the rocket but may also come down with the stick. The encyclopedic mind holds too many "dry clinics" which soon develop into sterile husks of medical thinking and reasoning. Hold more steadily to the homely values of simple judgment and practical insight if you are encyclopedic. Resist the temptation to dys-intellectualism, refrain from looking down your intellectual nose; avoid picayune argument; avoid the tendency to show the supercilious stance and to accuse dissenters of "intellectual dishonesty." This is a self rationalization which may degenerate into a cheap and pathetic pose.

We now come to a third and most familiar proclivity—the classmate who by the grace of God and not by reason of having taken a course in psychobiology is endowed with a ductile ease in getting along with people. If you are so gifted, you are blessed with a rich intuitive knowledge of human nature and a reflex-like facility in saying the appropriate thing at an appropriate time. So potent are these values that they have made some men of medicine demigods. But let them not be matched grain for grain by an equal weight of factual knowledge and they develop fatal toxic properties, making of men conceited fools and dangerous buffoons.

If you are of this ilk, a loose empiricism in practice is your greatest temptation. It's so deadly easy to rely on the oily word and the light touch of a solicitous hand, to bank on too much intuition. So easy to gravitate without too much strain of the conscience into that dangerous borderland between a flimsy empiricism and a frank charlatanry. Less excusable is your position than that of the quack, for unlike you he cannot conceal his lechery behind the robes of legitimate medicine.

A HAPPY BLEND OF HUMAN INGREDIENTS

Over in the corner and probably in the back row, unless you are alphabetically arranged, is the modest, level, plodding member of the class, who is perhaps a little lusterless but who studies quietly and passes his courses without fanfare or scintillation. His tempo, perhaps, is a little slow but it is steady. There are no spurts of brilliance, neither are there demonstrations of failure. Call him average, if you will, or even worse: he will continue his even mien through a prescribed routine. In some quiet by-way or in a village street you will shortly see his name plate. Not enough has been written about the average man. Pray, where would be the brilliance and erudition of great clinicians and teachers if these could not be contrasted against a somber setting of substantial, average men who practice medicine in an average town in an average way? Take heart, if the world stamps you as average, for if your virtues are not strongly positive then it follows that your weaknesses are likewise bland and forgivable.

In substance I do not believe that the class of 1941 possesses some of the startling hybrids I have just described. Yet these trends are there to some degree. I know that you are a happy blend of human ingredients wherein every good attribute is made stronger by reason of its constant tension with an undesirable one. Like carbon in steel, your weaknesses will give tensile strength to character.

If you truly believe that here, today, you begin to be what you are to be forever, how absorbing and fascinating will be your prospects! Give the lie to the claim that physicians so drug themselves with the routine of the sickroom that they become inarticulate in the drawing room. Conversation is a traffic and, if you enter it without some stock of knowledge, the trade drops off. To obtain knowledge, one must read. The physician, if his reading time is restricted, should by preference read the newest works in science, in literature the oldest. New books revive and redecorate old ideas; old books suggest and invigorate new ideas.

INCENTIVES AND REWARDS

Money, gratitude and technical success cannot be your only awards. Education, philanthropy and industry are deeply tinged by medical analogies and medical ideals. The newspapers are full of medical items and articles. Almost any medical book can get itself published. It is fair to say that no other profession excites today so large a measure of public interest in all classes. On this wave of public interest the medical profession is riding either for good or for evil result. To keep medicine in fashion it must continue to merit the public sympathy and approval. We charge you to strengthen your resolves and sharpen your wits to keep it so.

INTERN LABORATORY EDUCATION
IN THE GENERAL HOSPITAL

Condensation of a paper by Herman H. Van Horn, M.D., published in the Pennsylvania Medical Journal, November 1941, page 136.

The intern who comes to us in July for one year of postgraduate work is not a usual person. He is one of six thousand a year from a population of one hundred and forty million. He has an unusual background. He is a product of one of the most high pressured educational institutions in the world—the American medical school. For eight years since high school he has been in training, his instructors have included leading men of the country in medicine and surgery and, incidentally, his expense has amounted to several thousand dollars.

Moreover, this postgraduate student has a historical background as striking as any other portion of all educational history. In the last quarter of the nineteenth century microbiology was born and modern medicine became a fact. Laboratories, microscopes and full time instructors became essential factors in the modern advance. Then from 1900 to 1910 a cyclone of reformation struck the medical schools of this country, and those which survived began a remarkable metamorphosis into the powerful educational units that they are today. Also in that first decade of this century came the Council on Medical Education and Hospitals, which in 1904 inaugurated the intern year in the general hospital. Thus the general hospital was drawn into the picture, and to it was added an educational function. Today, if a general hospital is fortunate enough to be on the relatively small approved list of teaching hospitals, a large and definite educational responsibility is placed on its doorstep each year in July when the interns arrive. The nature of this responsibility has been well analyzed in THE JOURNAL by Nathan Smith and placed squarely where it belongs—on the shoulders of two groups: (1) the hospital administrators and (2) the members of the staff.

I can speak only for the course in laboratory education. I believe that it is well at the beginning of the year to file with the superintendent a written outline of what I hope to teach the intern and how I expect to do it. This is of interest to the superintendent and also tends to clear the matter in my own mind.

The aim of this course is to produce a physician so trained by his eight weeks in the laboratory as to be truly skilful in the laboratory part of his diagnostic work. The aim is to avoid a gap between the future physician and the laboratory, which he will so much need at the future time. In this course he will be taught a knowledge of some forty-five fundamental tests and will do them so frequently that they

will become a part of his equipment. He will learn the value of laboratory tests in their true perspective and not expect them to take the place of history, inspection, reflection, palpation, auscultation and percussion. He will learn to order the tests which are diagnostic rather than those of slight or remote scientific interest. He will learn that orders for laboratory work should come when and only when the history and physical examination are fresh in mind and call specifically for this or that test. He will learn that negative results from laboratory work are of little value and may sometimes be ignored in the face of other evidence. He will learn to reorder at proper intervals those tests which are helping to check the clinical changes in his patient. He will also learn that laboratory tests cost some one labor, time and material, have definite economic value, and must be paid for by his patient even as his medical bill must be paid. This will deter him from unnecessary expense to his patient. He will learn to use simple tests rather than complicated ones, when just as much can be learned from them.

To work out a method to attain this high aim and do this work in eight weeks is no mean problem. After talking with other pathologists, I discovered a teaching method being worked out in 1940 by a pathologist who felt as I did and who was introducing it in a teaching hospital in New York. This method appears to me as ideal as possible for this work in this period of time. There are four points in this method:

A separate work space must be provided for the intern and adequately equipped for his procedures. This may be known as the intern laboratory. If an entire separate room is not available, a corner of some other room can be utilized and complete equipment installed. This can be done at an expense of about \$400, and in 35 square feet of space. Such a laboratory can readily be created in any teaching hospital. I used a corner of a room adjoining my main laboratory. This assures the intern privacy and a chance to think. It also definitely avoids confusion in the main laboratory, where every one is busy.

We proceed in this course to give the intern during the first one of his eight weeks a working acquaintance with forty-five of the most fundamentally diagnostic tests that are done in a clinical laboratory. We ask him to bring to us on his first day in the laboratory a list of the

tests which he has learned in his medical course and which he feels competent to do. This list may be short—mainly blood counts and urinalyses. This does not matter. A technologist is assigned to introduce him to his laboratory and equipment and check with him on the tests he has already done to find if his technic can be improved. He is then given a list of forty-five tests by the pathologist, who discusses these tests with him and explains more fully the nature of this course. With the aid of the technologist these tests should be done by him, some six or seven a day during the first week. There is no doubt that this will be a busy week for him and will take most of a technologist's time, but it can readily be done.

Having thus refreshed his mind as to laboratory tests and technical methods, the following seven weeks are utilized as follows: From ward patients in various services a list is selected. As far as laboratory work is concerned, these will be his own patients. The list may be made small or large but should be as large as his time will permit. All orders on these patients will be given to him as soon as received in the laboratory. He will learn to know these patients and to do and report whatever laboratory work is requested on them at any time. He may also do other tests on them if he is so inclined. Thus for seven weeks he will be correlating laboratory tests with individual patients. Findings and diagnoses as well as surgical specimens will be discussed with the pathologist, other interns and staff men in the services. This follows and continues the educational principle of correlation, which was the basis of all his various clerkships in medical school.

Beyond this main line of work covered by the preceding three points there are a variety of special procedures for which the laboratory intern will find time as the occasion arises in ward cases. He will do lumbar punctures, gastric studies, duodenal drainage, blood transfusions and studies in allergy. He will do the current autopsies, under supervision, and with special reference to routine sequential procedure and thoroughness. He will study microscopic preparations from the autopsies and will study gross and microscopic surgical specimens. He will also be asked to prepare and present specimens at clinical conferences. He also should keep a list of all the work he does each day for summarizing at the end of his course.

DO YOU KNOW WHAT PHYSICIAN—

1. Was the first physician in New England arriving on the Mayflower?
2. Was the first to practice midwifery in America on a scientific basis?

3. Was the author of the first publication on a medical subject in America?
4. Was a famous explorer?

(The answers are on page 2290.)

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

Joint Meeting of Association of Medical Students and the Intern Council of America

The Association of Medical Students and the Intern Council of America will hold their annual meeting jointly at International House, University of Chicago, December 27-29. The general theme of the meeting will be "Health and the Defense of the Nation." Among the speakers will be Drs. Morris Fishbein, Chicago, editor of *THE JOURNAL*; William D. Cutter, Chicago, secretary of the Council on Medical Education and Hospitals; Fred C. Zappfe, Chicago, secretary of the Association of American Medical Colleges; Victor Johnson, dean of the University of Chicago College of Medicine; Charles S. Bacon, professor emeritus of the University of Illinois College of Medicine, Chicago, and Henry Sigerist of Johns Hopkins University School of Medicine, Baltimore.

Yale Increases Elective Hours of Study

On recommendation of the committee on program and policy, Yale University School of Medicine, New Haven, Conn., has revised the curriculum by establishing a two to one ratio between required and elective hours of study, so that about eight hundred hours a year will be allotted for required work and four hundred hours for elective work. The required courses will be held in the mornings only during the first two years of study, leaving all the afternoons free for elective courses. The number of hours of required work in the medical school mounted steadily for the past ten years until the time left for elective courses was less than one hundred and sixty hours for freshman and sophomore students and no time for third year students unless they voluntarily remained in school through the summer. Dean Francis G. Blake of the school of medicine, according to the *New York Times*, said of the foregoing change that "the revision of the curriculum is a reaffirmation and a further elaboration of the liberalized educational program which was initiated at Yale in the early 1920's and based on the fact that the medical student as an adult already has embarked on his life's work and therefore must learn both to pilot his own boat and assume largely the responsibility for acquiring that content of knowledge which is necessary in charting his future professional course. Dr. Samuel C. Harvey, professor of surgery at Yale and a member of the committee on program and policy, said that the formal lecture had decreased in importance in recent years because of the abundance and excellence of printed texts and that the lecture probably should be limited to work not yet available in printed form.

University of Kansas

Lewis L. Coriell '42 has been awarded the \$300 Porter Scholarship for 1941-1942 at the University of Kansas School of Medicine, Kansas City. The award is granted each year to the senior student with the leading scholastic record.—Francis O. Trotter Jr. '42 has been awarded the \$100 A. Morris Ginsberg prize in medicine. This award is made annually to the student who shows the highest proficiency in the medical courses of the junior year. The medical students were the guests of the local chapter of Phi Beta Pi at the annual fall medical school party at the Ambassador Hotel, Kansas City, October 8.

Minnesota's Incus Society

At the annual initiation banquet of the Incus Society, an undergraduate medical group at the medical school of the University of Minnesota, Minneapolis, Dr. Harold S. Diehl, dean and professor of preventive medicine and public health, and Dr. John C. McKinley, professor of medicine and nervous and mental diseases, gave addresses on the proposed revision of the junior and senior curriculums. The plans of the Incus Society for the year include (1) publication of a student section of the Minnesota Medical Foundation *Bulletin*, (2) symposiums on national defense, tuberculosis and the specialties, (3) the furtherance of closer student-faculty relations.

Names of British Medical Students in American Schools

Bombing attacks on London and other cities of the British Isles have damaged medical schools and hospitals in which medical students have received their clinical training. In order to help British medical students to continue their studies, the Rockefeller Foundation has created a number of studentships which provide for tuition and other instruction fees and living costs for a period not to exceed three years. Recently twenty-five British medical students were selected from a list of about one hundred to pursue their studies in medical schools in the United States and Canada. The students were chosen by a special committee in England, of which Sir John Stopford, vice chancellor of the University of Manchester, is chairman. These students are all British citizens and expect to return to the British Isles at the termination of their training. The names of the students and the medical schools at which they are now studying follow:

NAME	SCHOOL
Badenoch, John	Cornell
Bartley, Christopher W.	McGill
Cadman, Ewan F. B.	Washington (St. Louis)
Davies, Jack	Iowa
Edwards, David A.W.	Michigan
Gibson, James B.	Western Reserve
Gosling, Robert H.	Cornell
Gray, Ian R.	Wisconsin
Hare, Patrick J.	Johns Hopkins
May, Philip R. A.	Stanford
Newton, Michael	Pennsylvania
O'Hea, Matthew A.	Washington (St. Louis)
Pond, Desmond A.	Duke
Rankine, George	Duke
	Chicago
	Rochester
	Yale
	Johns Hopkins
	Harvard
Shillingford, Jack P.	Minnesota
Stephen, James D.	Harvard
Stowers, John M.	California
Swyer, Gerald I. M.	Pennsylvania
Tanner, James M.	Toronto
Todd, Ian P.	Yale
Turner, Robert	

Georgia Student Council

The Faculty-Student Council of the University of Georgia School of Medicine, Augusta, held its first meeting of the year, November 17, at the home of the dean, Dr. G. Lombard Kelly. It was reported that the hospitalization insurance plan instituted at the school last year had proved successful so far, the individual charge of \$2.50 taking care of all student hospital bills and leaving a small surplus.

THE UNIVERSITY MEDICAL CENTER WESTERN RESERVE UNIVERSITY CLEVELAND

Western Reserve University

Western Reserve University School of Medicine, Cleveland, controls for teaching and investigation purposes the clinical material of several hospitals whose bed capacity totals 2,600 and whose dispensaries are attended by 40,000 persons a year. The number of medical students at Western Reserve at present is 294. The school has graduated a total of 3,799 students "in course" and the schools which were consolidated with it graduated 1,218 students. The school of medicine of Western Reserve University was organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College; it is supported largely by endowment and special contributions, the income from tuition and fees covering but a minor part of the current budget. When the developments of medical science made the old building inadequate and accentuated the importance of close proximity to the other departments of the university, there evolved the conception of a university medical center, situated on the university campus and including not only the school of medicine with a group of university hospitals and clinics but the schools of the allied professions of nursing, pharmacy, dentistry and applied social sciences. In 1915 about 20 acres of land was secured for the medical center and since then the various buildings illustrated have from time to time been erected. While Mr. Samuel Mather and the General Education Board of the Rockefeller Foundation made magnificent contributions, it is interesting that many of the new buildings in the medical center were provided for by public subscription.

Effective July 1, 1940 the Lakeside Hospital, the Babies and Children's Hospital and the Maternity Hospital consolidated as University Hospitals of Cleveland. While the Rainbow Hospital for Crippled and Convalescent Children remains a separate institution, it also is operated by University Hospitals. In addition to the hospitals in the medical center, the university has control of the clinic material at the fifteen hundred bed Cleveland City Hospital, at the three hundred bed St. Vincent Charity Hospital and at the Ohio State Hospital for the Insane in Garfield Heights.

Western Reserve University School of Medicine is now the legal successor to all the regular medical schools that have existed from time to time in Cleveland, including the medical department of Wooster University, the medical department of Ohio Wesleyan University and Charity Hospital Medical College. Admission to the school is restricted so that the number of students in the upper classes ordinarily will not much exceed sixty. The total necessary expense, exclusive of tuition and fees but covering books and instruments, board and room, for thirty-four weeks need not, according to the official bulletin of the school, exceed \$600. The outlay for clothing, traveling expenses and incidentals depends on the student. A deposit of \$100, one fifth of the tuition of the first year, must be made by the applicant when he definitely accepts a place in the school, and this deposit is applied to the first payment on tuition if the student matriculates. The library, fellowships, loan funds, prizes, lecture foundations, student health service and many other facilities at the school are described in the November 1 issue of the *Bulletin* of the Western Reserve University School of Medicine.

Commencement Prizes at Washington University

At the 1941 commencement at Washington University School of Medicine, St. Louis, the following prizes were awarded: George F. Gill Prize in anatomy, \$50, to Bryce Harold Bondurant; George F. Gill Prize in pediatrics, \$50, to Jane Aral Erganian; Alpha Omega Alpha Book Prize to Leon Kahn; Howard A. McCordock Book Prize to Raymond Ray Lanier Jr.; Alexander Berg Prize in bacteriology, \$100, to Herman Theodore Blumenthal and Hyman Bernard Stillerman.

The Alumni scholarship for the school year 1941-1942 has been awarded to Donald Huelsmann; the T. Griswold Comstock scholarship to Raymond F. Rose; the Andrew R. and Susie Fleming Fund award to Jean R. Boyle; the George F. Gill scholarships to Edward W. Czebrinski and Harold Grant; the Williams McKim Marriott Memorial scholarship to William J. Davis; the Eliza McMillan scholarship for women to Dorothy Reese; the LaVerne Noyes scholarship to Saul D. Silvermintz; the Robert Allen Roblee scholarships to

Robert E. Holt Jr. and Helen C. Reller; the Jewish Women's scholarships to Bernard Bressler and David Feldman, and the John B. Shapleigh scholarship to John H. Eisenhauer.

Two British medical students were admitted to the third year class as Rockefeller Foundation scholars. They are Ewan F. B. Cadman of Southport, Lancashire, England, and Matthew O'Hea of Wishaw, Scotland.

Northwestern

The annual Founder's Day Lecture at Northwestern University Medical School, Chicago, was given this year on October 7 in honor of Dr. Irving S. Cutler, the retiring dean. The new dean, Dr. James Roscoe Miller, gave the address which expressed for the school its appreciation of the work and life of Dr. Cutler, on whom at this occasion the president of Northwestern University conferred the degree of Doctor of Science. The faculty presented to Dr. Cutler a book containing the signatures of all its members and a message of gratitude.

A new course entitled "Military Medicine" has been added to the senior year; four lectures will be given by officers of the army and navy and twenty-eight lectures by specialists at Northwestern University on medicomilitary problems.

Student Clinic Day at Wayne

Regular classes were dismissed to permit students, faculty and alumni to participate in the fourth annual Student Clinic Day at Wayne University College of Medicine, Detroit, December 12. The students were in charge in the clinical sessions on heart sounds, high blood pressure, the electrocardiograph and contagious diseases. The general chairman was junior student Wellington B. Huntley. The program began at 8:30 a. m. and continued throughout the afternoon. Cash prizes and medals were awarded to the students who contributed outstanding papers or clinical leadership to the day's program. At the dinner meeting in the evening at the Wardell Hotel, S. L. A. Marshall of the *Detroit News* spoke on "The War Today." Other dinner speakers were Dean Edgar H. Norris, M.D., and Associate Dean William J. Stapleton, M.D.

A. O. A. at New York University

Under the auspices of the Delta chapter of Alpha Omega Alpha, Dr. William C. Stadie, associate professor of research medicine at the University of Pennsylvania School of Medicine, discussed fat embolism in diabetes mellitus on October 31. After the lecture the following newly elected members of the society were welcomed: Class of 1942: David A. Dreiling, Saul J. Farber, Arnold W. Friedman, Robert M. Gabrielson, Irma H. Gross, Carol K. Smith, Harvey P. Kopell, Harold Lief, Doris H. Milman, Alice E. Moore, David F. Sunkin; Class of 1943: Ernest Cottle, Jerome Seides, Leon Sokoloff.

The Agramonte Manuscripts at Louisiana

Dr. Philip S. Hench, Rochester, Minn., who is preparing a monograph on the work of the U. S. Army Yellow Fever Commission, recently visited the Aristides Agramonte Memorial Library at the Louisiana State University School of Medicine, New Orleans, in order to examine manuscripts and papers of Dr. Agramonte, who was a member of the U. S. Army Commission that demonstrated the transmission of yellow fever by means of a certain species of mosquito. Dr. Hench had just returned from a visit to Dr. Agramonte's daughter in Havana, Cuba.

Syracuse

The new initiates into Alpha Omega Alpha at Syracuse University College of Medicine are William N. Hamblin, Paul Rousseau, Michael P. Rizzuto and Alson F. Pierce, all of the class of 1942, who together with J. Benton Pike and Erwin R. Centerwall, former initiates, comprise the active chapter at Syracuse. This organization will provide a series of programs open to the entire student body and faculty in which members of the local chapter will present scientific papers. At the first of the series for this year on November 13 J. Benton Pike gave a paper on renal hypertension.

Dr. Harry Goldblatt, professor of experimental pathology at Western Reserve University School of Medicine, Cleveland, discussed experimental hypertension, December 9, in the first of a series of lectures sponsored by the local chapter of Nu Sigma Nu medical fraternity and open to the entire student body.

The Harriman scholarship, which is awarded each year to one of the five top ranking students in the senior class, was awarded this year to Paul Rousseau.

"DO YOU KNOW WHAT PHYSICIAN"

Following are answers to the questions appearing on page 2287:

1. Samuel Fuller (1580-1633), who studied medicine in Leyden. Dr. Fuller then practiced in New England until his death in 1633.
2. Dr. James Lloyd (1726-1810), who was born on Long Island, New York, and after a preliminary education in a private school at New Haven was apprenticed in medicine for five years to Dr. William Clark of Boston. He attended lectures on midwifery in London for two years and also acted as a "dresser" at Guy's Hospital in London, where he worked with William and John Hunter. He was in practice in Boston at the time the Revolutionary War broke out.
3. Thomas Thatcher (1620-1678), who also was installed as the first minister of the Old South Church in Boston, Feb. 16, 1670. He was educated for the ministry, according to Dr. Benjamin Spector's book "One Hour of Medical History," volume 5, by Charles Chauncy, the second president of Harvard College, and it is said he probably received his medical education from the same source. In 1677 he issued a publication entitled "A Brief Rule to Guide the Common People of New England how to order themselves and theirs in the Small-Pocks, or Measles."
4. David Livingstone (1813-1873), who studied medicine in London and in 1840 sailed on the first of his great expeditions to Africa. He was absent from England from that year until 1856, again from 1858 to 1864 and again from 1865 until his death at Ilala on Lake Bangweolo in 1873. He made many important geographical discoveries in Africa and was noted for his kindness and tact in dealing with the natives and for the intensity of his desire to open up Africa so that the slave trade might be brought to an end. Among his publications are "Missionary Travels and Researches in South Africa," in which is an accurate account of the tsetse fly disease, and "Narrative of an Expedition to the Zambesi and Its Tributaries, and of the Discovery of the Lakes Shirwa and Nyassa." The well known meeting in Central Africa of Dr. Livingstone with Henry M. Stanley, who had been sent by the New York Herald to find Livingstone, took place in October 1871. The house in which Livingstone was born has been purchased by public subscription to be preserved in honor of this great missionary and explorer.

Book Notices

Essentials of General Surgery. By Wallace P. Ritchie, M.D., Clinical Assistant Professor, Department of Surgery, University of Minnesota Medical School, Minneapolis. Cloth. Price, \$8.50. Pp. 813, with 237 illustrations. St. Louis: C. V. Mosby Company, 1941.

The author admirably succeeded in condensing into a single volume the ever spreading field of general surgery. After a concise but comprehensive discussion of fundamental general problems such as anesthesia, surgical technic and asepsis, the common surgical lesions of different parts of the body, their diagnosis and methods of treatment are described in a masterly manner. No superfluous words are used, yet nothing is omitted that has a bearing on the subject. Although the book has been written primarily for the undergraduate student, it contains enough detail to have an appeal not only to a general practitioner but even to a surgeon who wishes to brush up on the latest advances in his selected field. Several chapters have been written by other members of the staff of the University of Minnesota Medical School, but all are characterized by the same features: brevity, clarity of presentation, easy style, good illustrations. Few errors and omissions of minor importance have been noticed. In the chapter on history of the development of surgery an inclusion of the names of Cushing, Chevalier Jackson and the Mayos would be advisable, because they widened the horizon of surgery in many directions. In the chapter on anesthesia, Luckhardt's name deserves a place because of the popularity of ethylene. "Hypertrophy is enucleated" (p. 724, fifth line from top) is incorrect phraseology, because hypertrophy is a pathologic process and not an organ which can be removed. Not only can the book be unhesitatingly recommended to undergraduate students, but undoubtedly it will make a fine acquisition to the libraries of general practitioners and surgeons as well.

Studies on the Etiology of Gallstones: A Subtilis-Like Bacilli-Group as an Etiologic Factor. By Karl Mårtensson. Akademisk avhandling för erkändelse av medicine doktorsgrad, Stockholm. Acta chirurgica Scandinavica, Vol. LXXXIV, Supplementum LXII. Paper. Pp. 227, with 74 illustrations. Stockholm: Nordisk Rotogravyr, 1941.

This is essentially a report of the results obtained in studies carried out to determine the relationship between bacterial infection and the formation of gallstones. The study was undertaken because it was noted that the center of gallstones was made up of necrotic-like epithelial cells and that, in the walls of gallbladders in which recent formation of stone had taken place, sporulating bacilli occurred intraepithelially and subepithelially with surrounding regions of necrosis and desquamating epithelium.

Considerable space is given to a general consideration of cholelithiasis. The composition and structure of gallstones is reviewed in detail, and a method is presented for analyzing the stroma of the gallstone without injuring possible existent bacteria. A chapter is devoted to the symptomatology and pathology of gallstones. The various theories of the etiology of gallstones are reviewed in detail, and attention is drawn to the possible connection between the formation of gallstones and systemic diseases and between the formation of stones and other disturbances. The literature is extensively reviewed in consideration of the various hypotheses advanced for the formation of gallstones.

Material for culture was obtained from diseased gallbladders removed at operation in 78 cases and at necropsy in 28 cases. A variety of organisms was isolated by this method, but the organism most often found proved to be a gram-positive, mobile endospore-forming rod which the writer chooses to call the "typical bacillus." This "typical bacillus" was recovered from the wall of the gallbladder, the bile, the gallstone itself and the intestinal tract.

The organism discovered and called the "typical bacillus" was thoroughly studied as to morphologic and biologic characteristics, and it was found that it could be divided into three groups, two of which are facultatively anaerobic, one being an obligatory anaerobe. The organism did not fit any previously known bacterium in all its characteristics.

In vitro experiments showed that the "typical bacillus" was capable of causing precipitation of cholesterol when inoculated

on sterile normal human bile. Definite gallstones were produced experimentally in rabbits, swine, sheep and cattle following the inoculation of cultures of this bacillus. All the types of biliary calculi found in man were obtained. "Typical bacilli" were cultured from gallstones experimentally produced, and these organisms when injected into animals were able to give rise to gallstones. The organism was administered directly into the lumen of the gallbladder, intravenously, subcutaneously or orally; all methods were effective in the production of gallstones.

An antigen was prepared with a spore free culture of dead bacilli, and rabbits were thus immunized against the "typical bacillus." In none of these rabbits did biliary calculi develop subsequent to the injection of gallstone producing doses of the bacillus directly into the lumen of the gallbladder. The author expresses the belief that this indicates that the formation of gallstones is affected by the specific antigen of the typical bacillus.

This report is interesting and deserves verification and further clarification by independent workers. The work seems to have been well performed and the results well controlled. The results obtained lend further evidence to substantiate the infectious theory of the formation of gallstones.

A Text-Book of Pathology. Edited by E. T. Bell, M.D., Professor of Pathology in the University of Minnesota, Minneapolis. Fourth edition. Cloth. Price, \$9.50. Pp. 931, with 433 illustrations. Philadelphia: Lea & Febiger, 1941.

This edition follows the same general plan as the earlier editions. The first portion (approximately 40 per cent) is devoted to general pathology, the remainder to special pathology. The text has been increased by thirty-eight pages, and forty-one new illustrations have been introduced.

Certain commendable changes have been made. The chapter on diseases of the urinary system has been thoroughly revised, and Bell's classification of renal disease has been somewhat modified. The discussion of renal diseases remains probably the best to be found in any standard textbook. That portion of diseases of the heart which concerns congenital disorders has been rewritten and remains an excellent chapter. The chapter on diseases of the blood has been written by Bell in this edition but remains essentially the same as formerly presented by Hal Downey except for expansion of certain portions and a shift in emphasis from histogenesis to differentiation of blood cells.

The following criticisms seem worth recording: Although pathologic physiology has received considerable attention in this volume, such disorders as shock, hypovitaminosis, acid base unbalance and uremia receive but little attention. The problem of aging, which is receiving more and more general consideration, is not dealt with here. Bell's general discussion of tumors is excellent: his treatment of specific tumors, however, often includes insufficient histopathology. The general discussion of tuberculosis is probably inadequate for the beginning student. Hypertrophy, hyperplasia and metaplasia are not treated as fundamental processes. In Bell's discussion of edema it is unfortunate that certain outmoded physiologic concepts are retained and that more emphasis is not given to the role of injury in causing increased capillary permeability. Toxic cirrhosis has been inadequately treated, and cardiac cirrhosis is not mentioned. Only five lines are devoted to the general subject of focal necrosis of the liver; four times this much space is spent on cystic degeneration of the same organ. Another example of disproportionate emphasis is encountered in the two and one-fourth page discussion of malaria, in which but five lines deal with morphologic changes.

Worthy of special commendation are gynecologic pathology, diseases of the spleen and the mycoses. In these and other chapters a brief introductory review of histology and physiology is employed to good advantage. The subject of fundamental phenomena of inflammation is well presented by Bell, and his discussion of syphilis is very good. The illustrations are excellent from the point of view of both quality and selection. The bibliography which follows the discussion of each general subject has been well chosen and is particularly valuable because of the explanatory notes which accompany it. This will continue to be a valuable textbook of pathology, probably of greater usefulness to the advanced student, however, than to the beginner.

Über funktionelle Veränderungen der P- und T-Zacken im Elektrokardiogramm: Experimentelle Untersuchungen mit Ergotamin und Amylnitrit, sowie klinische Beobachtungen. Von Olof Nordenfält. *Acta medica Scandinavica. Supplementum CXIX.* Paper. Pp. 186, with 17 illustrations. Lund: Håkan Ohlssons Boktryckeri, 1941.

In this extensive monograph with an English summary the author presents his investigations on the changes in the electrocardiogram due to certain functional disorders. He first reports on the effects of posture change from lying to standing in 49 subjects before and after the injection of 0.5 mg. of ergotamine. This included 14 patients with orthostatic hypotension. In all subjects, but more marked in the orthostatic patients, definite changes in the electrocardiogram appeared. Ergotamine was found to lessen noticeably the postural alterations in the electrocardiogram. This suggested that the action of posture change does not operate through the production of coronary insufficiency but through a direct action on the heart, reflex in origin and sympathicotonic in character. The author then relates his experience with the inhalation of amyl nitrite by 21 normal young persons and by an older person with complete heart block. Again changes in the electrocardiogram were found associated with the cardiac acceleration and drop in blood pressure, changes that resembled those seen in the orthostatic patients on posture change. On this account the author concludes that the mechanism in the two groups is the same.

In the next section he reviews the electrocardiographic changes following exercise carried out on 10 normal persons. The exercise consisted in running up to the point of marked cardiac palpitation. The electrocardiographic changes after exercise were similar to those in the preceding experiments and are again ascribed to an increase in the sympathicotonic state.

The author next reviews the literature on the influence of the autonomic nervous system on the electrocardiogram and then briefly discusses the physiology of coronary vessels. This analysis in the author's mind supports his previous contention of the neurogenic origin of the electrocardiographic changes. Since the vagi appear not to go to the ventricles, the changes seen following vagus stimulation is attributed to a decrease in the sympathicotonic state. Increase in the sympathicotonic state causes cardiac acceleration, a taller P wave especially in leads 2 and 3, a shorter PR, a slight depression of the S-T segment, a marked decrease in the size of the T wave which may become diphasic or inverted and a relative prolongation of electrical systole.

While the argument that coronary insufficiency is not involved in these electrocardiographic changes is supported by the author's experience, the possibility is not excluded in the opinion of the reviewer that the change in autonomic nervous tone may operate by changing the caliber of the coronary vessels rather than, as is suggested, by a direct action on the heart muscle. Nevertheless the view expressed by the author is one well worth considering.

Perhaps the most important contribution of this detailed study is the suggestion that 0.5 mg. of ergotamine given intravenously or subcutaneously may be used to differentiate between the reversible functional electrocardiographic changes and the irreversible ones based on organic disease of the heart. It is now clearly recognized that, in fear and in neurocirculatory disorders of the heart, electrocardiographic abnormalities are found resembling those seen in coronary insufficiency. A more extensive trial of ergotamine as suggested by the author may turn out to be of clinical value in the differential diagnosis. The experience of the author, however, is insufficient to warrant this final conclusion.

Microbes Which Help or Destroy Us. By Paul W. Allen, Ph.D., Professor of Bacteriology and Head of the Department, University of Tennessee, Knoxville, D. Frank Holtman, Ph.D., Associate Professor of Bacteriology, University of Tennessee, and Louise Allen McBee, M.S. Cloth. Price, \$3.50. Pp. 540, with 115 illustrations, including 13 color plates. St. Louis: C. V. Mosby Company, 1941.

This book is another of the popular presentations of bacteriology as it relates to both the infectious diseases and the various phenomena of bacterial etiology that are beneficial to man. The material is soundly and clearly presented in an informal way and should be readily understood and enjoyed by the intelligent layman. The style is somewhat strained in the attempt to popularize, e. g. "our microscopic pals," but, though slightly irritating to the scientist, is perhaps desirable here. To one

trained by systematic study of the bacteria, the organization of the book as a whole seems somewhat confused. For example, a number of chapters intervene between the discussion of water supplies and that of sewage disposal; bacteriophage is discussed in a separate chapter at the end of the book rather than with the viruses; the spirochetes of Weil's disease are widely separated from *Treponema*. Such an illogical development will, of course, be hardly apparent to the layman. Much of the material on the infectious diseases is discussed in terms of particular pathologic conditions. There are, for instance, chapters devoted to the bacteriology of appendicitis, conjunctivitis, boils and carbuncles, tooth infections and the like, all of heterogeneous etiology. Whether such an arrangement is to be preferred in a popular presentation to one of suppurative infections, infections of the upper respiratory tract, the enteric diseases and the like is open to question. In a few instances questionable statements are made; the genesis and development of the epidemic wave, for example, are accounted for entirely in terms of variations in virulence—a belief vigorously expounded by some but for which there is no direct evidence. Questionable statements are rare, however, and neither are serious nor do they detract from the presentation as far as the layman is concerned.

The book is well made and attractively bound. Portraits comprise a large part of the illustrations, and there are thirteen excellent color plates taken from other books issued by the same publisher. The black and white pictures are somewhat below standard, as a rule, but some, such as figures 9 and 10, are superb. The physician will find this book of little value as a source of information because of its elementary nature but may recommend it to the inquiring layman as a clear, accurate and informative discussion devoid of the attempts at sensationalism characteristic of some books of this kind.

Annual Review of Biochemistry. James Murray Luck, Editor. James H. C. Smith, Associate Editor. Volume X. Cloth. Price, \$5. Pp. 692. Stanford University P. O.: Annual Reviews, Inc., 1941.

A book which has been almost indispensable since its inception in 1932 is the Annual Review of Biochemistry. This volume presents the status of certain subjects in the biochemical field in such terms that interest not only by chemists but by practically all laboratory and clinical investigators in almost every field of biologic science is the ultimate response. The present edition reviews the more recent developments in a number of biochemical subjects by offering twenty-four articles which have been written by authorities in their respective fields of endeavor. The topics are biologic oxidations and reductions, proteolytic enzymes, nonproteolytic enzymes, chemistry of the carbohydrates and glycosides, chemistry of amino acids and proteins, the chemistry and metabolism of the compounds of sulfur, carbohydrate metabolism, fat metabolism, the metabolism of proteins and amino acids, the biochemistry of the nucleic acids, purines and pyrimidines, the biochemistry of creatine and creatinine, detoxication mechanisms, hormones, the water-soluble vitamins, fat-soluble vitamins, nutrition, relation of soil and plant deficiencies and of toxic constituents in soils to animal nutrition, mineral nutrition of plants, plant growth substances, spectrometric studies in relation to biology, review of bioluminescence, the chemistry and metabolism of bacteria, biochemical nitrogen fixation and properties of protein monolayers.

It is not possible in a book review to present more than a glimpse of the material contained in such an informative work as this volume. Those who are familiar with past editions will need no urging to peruse the pages of the present edition. Those who have not been very intimate with the companion volumes will be well repaid if they avail themselves of a copy. Members of the medical profession will be especially interested in the sections dealing with the metabolism of fat, proteins and amino acids, detoxication mechanisms, hormones, vitamins and nutrition. For example, in the section relating to hormones there may be found a survey of the present status of thyroxine, the adrenal cortex, progesterone, estrogens, androgens and the anterior pituitary gland. In general, each hormone is discussed under isolation and partial synthesis of derivatives, physiologic effects and assays. As in the past, this edition can be highly recommended as an authoritative treatise on recent developments in biochemistry, and a copy should be available for all lecturers, students and clinical and laboratory investigators.

The Man Who Lived for Tomorrow: A Biography of William Hallock Park, M.D. By Wade W. Oliver. Cloth. Price, \$3.75. Pp. 507, with portrait. New York: E. P. Dutton & Co., Inc., 1941.

This is the biography of a man whose name has been associated with progressive preventive medicine and public health practices for almost fifty years. Dr. William Hallock Park began his career in this field as a member of the New York City Department of Health and there remained for forty-six years before retiring in 1936. As is so often the case with medical men who later become authorities in their respective specialties, Dr. Park had no intention of choosing this career when he graduated; on completing his internship he spent a year of special study in Europe, returning to begin the practice of otolaryngology. Because of a disagreement on the etiology of diphtheria voiced during a social call on Dr. Prudden, Park was invited to work in Prudden's quarters and there demonstrated that the Klebs-Loeffler bacillus is the cause of the disease. At that time this organism was not generally accepted as the responsible agent. This marked the beginning of a career that was to play an important part in public health.

Although many will remember Dr. Park as the first to produce diphtheria antitoxin outside of Europe, others will associate him with general measures on diphtheria control and with studies on cholera, tuberculosis, meningitis, encephalitis, poliomyelitis, pneumonia, whooping cough, streptococcal infections, rabies, tetanus, influenza, typhoid and other infectious hazards to public safety.

Author of recognized textbooks on bacteriology and hygiene and public health, Park's preeminence was cited on Oct. 6, 1936, when the William Hallock Park Laboratory of the New York City Board of Health was dedicated in honor of his retirement as director of laboratories. Among the letters forwarded to Park on this occasion was one from the late Dr. Hans Zinsser, who wrote "Your accomplishments in the introduction of diphtheria antitoxin in this country and in the organization of what was then the model public health and research laboratory in the United States are matters of record, but there are other things you have done which are known only to those of us who were influenced by your example, your advice and your personality. There are many of us—but few who owe you more than I do." Holder of numerous awards and honors, one of which was knighthood bestowed by King Alfonso XIII of Spain, he enjoyed an international reputation that is well described in this biography.

The author is to be congratulated on his practice of frequently quoting from correspondence concerning events which transpired in Park's life. This serves the twofold purpose of emphasizing the work of a leader in public health and of affording interesting and authentic reading in a fashion not commonly found in current biographies. It is a book which is a worthwhile addition to any library, as it presents more than the story of one man's life; it offers interesting sidelights on the development of many of the preventive medicine measures now employed in the United States and elsewhere.

Torch & Crucible: The Life and Death of Antoine Lavoisier. By Sidney J. French. Cloth. Price, \$3.50. Pp. 285. Princeton: Princeton University Press; London: Oxford University Press, 1941.

Lavoisier is best known as "the father of modern chemistry," but he was one of the leading men in his day for other reasons as well. He was formally educated for the law but had more interest in science, especially geology, water supplies and water, with the result that he was elected member of the Academy of Science at the age of 25. In his work with water and gypsum he weighed his materials with the greatest care, a new quantitative procedure that in his hands led to the overthrow of the centuries old phlogiston dogma of combustion and to the introduction of quantitative methods in chemistry, by means of which he discovered the composition of the air and its relation to life. His investigations laid the foundations of chemical physiology. He changed completely chemical thought and nomenclature. We owe the names oxygen and hydrogen to him. But in addition to his epochal achievements in the science of chemistry Lavoisier, always an active citizen with liberal and progressive tendencies, gave much time and energy to work of a public nature. He held membership in the "Tax Farm" (*Ferme générale*) of France and was a member of its committee on

tobacco. When the government took over the powder monopoly Lavoisier became the director of the powder commission and moved his residence and laboratory into the old arsenal of Paris. Here Madame Lavoisier presided with grace and charm over famous dinners. And Lavoisier had a country estate where he made successful experiments in agriculture and endeared himself to the people of the district. In his biography French has succeeded admirably in his attempt "to write in one person the elements which made Lavoisier such a striking figure." He gives us a vivid, absorbingly interesting account of the rise of Lavoisier's family, his personal life, character and career, in science as well as in public service and other relations. A strong light is thrown on the tremendous developments in the background that led to his execution, May 8, 1794, a victim of the revolutionary fury. He was then 50 years old. "It took but an instant to cut off his head; a hundred years will not suffice to produce one like it."

Professional Adjustments. I. By Gene Harrison, A.B., R.N., Educational Director, Druid City Hospital School of Nursing, Tuscaloosa, Alabama. Cloth. Price, \$2.25. Pp. 204. St. Louis: C. V. Mosby Company, 1941.

A student nurse, or better still a prospective nurse, will find this book of the utmost value to her. Based on the extensive experience of the author as a teacher of nurses and director of nursing schools, it deals with the everyday, commonplace matters which, taken separately, are of little consequence but which, added together, may make all the difference between a good nurse and an inferior one. Dealing with such matters as careless habits of speech, neatness and general conduct and discussing rouge, fingernail polish and other matters pertaining to appearance, it relates all these to the fundamental question as to what effect they will have on the character of the nurse and her service to the patients. In the same way the matter of alcohol, tobacco, chastity, personal relationships with fellow students and fundamental honesty of attitude toward hospital, patients, doctors and self are treated in a straightforward, simple, sincere manner which should be of genuine help to any student nurse. This book not only should be read by student nurses but might profitably be reread by some graduates and should certainly be recommended to the girl who looks on nursing as a prospective career. Since the book is intended for use in a course of instruction, it is organized into chapters to each of which is appended a list of suggestions for study and a bibliography for reference reading, as well as one or more pages for personal notes. An inspirational touch is furnished by a brief quotation opposite the opening page of each chapter. There is a good index.

The Baker Memorial: A Study of the First Ten Years of a Unit for People of Moderate Means at the Massachusetts General Hospital. By Haven Emerson, M.D. Cloth. Price, 50 cents. Pp. 75, with 2 illustrations. New York: Commonwealth Fund, 1941.

In 1930 the Baker Memorial Hospital introduced a plan for the hospitalization of middle class patients. The patient day rates were to be between \$4.50 and \$6.50 and the medical bill limited to approximately \$150 for any patient. In the ten years that followed, bed capacity has increased from one hundred and fifty-nine to two hundred and forty-nine and the percentage of occupancy from 54 to 86. The death rate has been about midway between that of the Massachusetts General Hospital and the Phillips House, with which institutions it is affiliated. Massachusetts General cares for charity patients and the Phillips House devotes itself to private patients. A questionnaire to discharged patients brought general expressions of satisfaction as to the treatment received with criticisms mainly confined to administrative details. The average patient payment during the ten year period for all inclusive hospital care was \$119.09 and the average medical fee \$66.06. While the Baker Memorial Hospital shows a small operating surplus, account has not been taken of depreciation or of sums contributed from the resources of the Massachusetts General Hospital. A considerable sum has also been contributed by the Julius Rosenwald Fund. There is no retirement or insurance plan for the administrative or non-professional staff. In view of the gift of \$2,000,000 for the original building and numerous other large gifts to meet deficits, it cannot be said that the Baker Memorial Hospital plan offers a pattern which can be followed generally.

Organic Chemistry with Applications to Pharmacy and Medicine. By Eldin V. Lynn, Ph.D., Professor of Chemistry, Massachusetts College of Pharmacy, Boston. Cloth. Price, \$4.50. Pp. 410. Philadelphia: Lea & Febiger, 1941.

For some years there has been need for a textbook on organic chemistry especially prepared for students who are engaged in the study of organic chemistry as an adjunct to pharmacy and medicine. This volume has been written to fill this need. The subject matter includes that usually found in organic treatises, but most of the material which is only of commercial or theoretical interest is omitted, while that which is of pharmaceutical or medical interest is emphasized. U. S. P., N. F. and N. N. R. products are so designated and their descriptions given, but only cursory reference is given to methods of analytic procedure.

The subject material is well arranged and a sufficient number of formulas and illustrations are given for clarification of the reactions. The organic compounds are divided into forty-four chapters according to chemical structure; the general characteristics of each group are given and important members are described individually. At the end of each chapter there are a number of review questions which deal mainly with reactions and identifications. In the interest of brevity, the descriptions not infrequently assume the character of an outline, which results in a lack of smoothness of presentation.

The book is of especial value to those organic chemistry teachers who have not had training in the medical or pharmaceutical fields and find difficulty in giving supplementary lectures on these subjects. To the student of medicine or pharmacy it is a textbook the contents of which can be studied as a whole without the necessity of omitting portions that are too far afield. Therefore it will be found useful not only as a book for the classroom but also as a reference work.

Health Resorts of the USSR: A Symposium of Articles Compiled from Data of the Central Institute of Balneology in Moscow. Editor: Dr. I. A. Pertsov. Cloth. Pp. 271, with illustrations. Moscow: The U. S. S. R. Society for Cultural Relations with Foreign Countries (V. O. K. S.), [n. d.]

This book leaves the reader in some doubt as to whether it is intended to promote the health resorts of the Union of Soviet Socialist Republics or to extol the October Socialist Revolution. It consists mainly of descriptions of various health resorts in the different autonomous Soviet Republics. These descriptions are almost purely promotional; one searches in vain for true scientific evaluation. For example, with respect to the resort Akhtala, one of the Georgian Soviet Socialist Republic's resorts, occur the following quotations, which are typical of the book:

Exuding from the hills, with a temperature of about 23°, the Akhtala muds have been found to consist of water and solid substances among which plastic clay predominates. The aqueous component of the mud is basically sodium chloride water, also containing carbonates of sodium, calcium, magnesium and so on, its mineralization totaling 16.5 Gm. per liter.

Akhtala mud is administered both in the form of hot baths and by bathing at the mud-mounds. It finds application for the treatment of diseases of the locomotor organs, chronic perigastritis, peridodenitis, hepatitis, perityphlitis, neuritis and neuralgia. These muds are also a remedial for treatment of skin diseases, chronic phlebitis, varicose ulcers, female diseases and other ailments.

Much space is devoted to pointing out the tremendous growth and reconstruction of the "culture and rest" facilities which are claimed to be open to all Soviet workers. The actual capacities and figures given for occupancy during recent years indicate that even yet these facilities are actually open to only a small percentage of those who are theoretically entitled to them.

This book is nothing more than a descriptive listing of Soviet spas with propaganda material for the Soviet political and economic system.

Immunity Against Animal Parasites. By James T. Culbertson, Assistant Professor of Bacteriology, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, \$3.50. Pp. 274, with 4 illustrations. New York: Columbia University Press, 1941.

The author intends this volume to be of value to those beginning the study of the fundamental principles of immunity in relation to the parasitic forms of life, but he assumes that the reader is well versed in the fundamentals of both parasitology and immunology.

The contents of the book are divided into an introduction and three parts: part one relates to resistance and acquired immunity, part two relates to immunity in specific diseases and part three

discusses applied immunology. In addition there is included a list of the abbreviations of names of periodicals and an adequate index. Part one discusses natural resistance, age resistance, specifically acquired immunity, requisites for immune response, parasites which elicit immunity, mechanisms of specific immunity and demonstrations of immunity; part two describes the immunity from the amebiasis, the leishmaniasis, the trypanosomiasis, the malaria, the coccidiosis, the trematodiasis, the cestodiasis, the nematodiasis and the arthropods and part three contains a classification of parasites, a description of vaccination against parasites and diagnosis of parasitic infection. The index is sufficiently extensive to permit easy reference.

The style of writing and the general makeup of the book are conducive to pleasant reading. Unnecessary details are kept at a minimum. The information contained in this book will be of interest and value to all students of immunity against animal parasites, and the volume can be regarded as an authoritative source for reference. Its availability in all libraries will be appreciated by students and lecturers.

A Laboratory Manual of Physiological Chemistry. By D. Wright Wilson, Benjamin Rush Professor of Physiological Chemistry, University of Pennsylvania, Philadelphia. Fourth edition. Cloth. Price, \$2.50. Pp. 298. Baltimore: Williams & Wilkins Company, 1941.

The book is designed as a laboratory manual for medical, dental and other students taking a general course in biochemistry. It follows essentially the same pattern as the three previous editions, which were reviewed in THE JOURNAL. Obviously the manual has been written primarily to meet the author's own requirements in teaching relatively large classes in biochemistry. Since the general plan remains unchanged, he has undoubtedly found that the book meets these requirements. The right hand page has been left blank for laboratory notes, thus cutting in half the number of apparently printed pages. The manual is confined almost wholly to directions for laboratory experiments, discussion and explanations being reduced to a minimum with the obvious intention of focusing the students' attention on the laboratory experiments. The directions are concise but given in sufficient detail so that they can be followed and understood. In general the course appears to follow the plan introduced by the Chittenden-Mendel school. The methods selected may be called standard methods. The author has been conservative in that the many advances in the field have resulted in few changes in the manual. He has apparently felt that, if the laboratory work furnished the student a sound ground work in the subject, other necessary material could be given in lectures and assigned readings. It is of interest and logical that he should have included carbohydrates, proteins and fats in part I, introduction, along with inorganic constituents, standard acid and alkali, electrolytic dissociation, colloids and alcohols, aldehydes and esters. Part II, which takes up the last two thirds of the book, includes the usual topics covered in biochemistry under the heading of Body Tissues and Fluids. A short discussion of photoelectric colorimetry has been included in this edition.

Basic Problems of Behavior. By Mandel Sherman, M.D., Ph.D. Cloth. Price, \$3. Pp. 440. New York, Toronto & London: Longmans, Green & Co., 1941.

This is a textbook for educators, psychologists and students of the social sciences. It is an elaboration of the author's *Mental Hygiene and Education*, published in 1934. The book aims "to present the clinical, experimental, psychological and psychiatric data of a number of basic problems of behavior." Individual chapters on the emotions, motivation and frustration, theories of personality, common mechanisms of adjustment, measurement of personality, attitudes and conflicts are followed by more clinical chapters on delinquent behavior, the neuroses and "mental abnormalities." The scope of the book is so broad that detailed critical review is here impossible. The author draws on his research and clinical experience and he culls and interprets the extensive literature, publishing a useful and well selected bibliography. The thesis that clinical and experimental observations or evidence can well be combined in the study of behavior is defended, but at times the author's prejudices lead him to turn against this point of view. This is particularly noteworthy in his repudiation of some psychoanalytic concepts which are "accepted on clinical evidence and . . . on com-

mon sense grounds" without "experimental or verifiable evidence" (p. 129). The implication is that psychoanalytic clinical observation is not verifiable. It is understandable, in view of the extensive range the book covers, that at times the discussion seems incomplete or superficial. The book is more authentic in the earlier chapters than in the later discussions of neuroses and psychoses. As an instance the author understates by far, if he at all appreciates, the role of aggression in the neuroses. The discussion of the neuroses is general and somewhat confused. The book will be useful to the general student of behavior as offering an orientation and guidance, particularly with respect to the literature. The medical student or student of psychiatry will find it of more limited usefulness.

Breathing Capacity and Grip Strength of Preschool Children. By Eleanor Metheny. George D. Stoddard, Ph.D., Editor, University of Iowa Studies, Studies in Child Welfare, Volume XVIII, No. 2. Paper. Price, \$1.35. Pp. 207, with 7 illustrations. Iowa City: University of Iowa Press, 1940.

Grip strength, as measured with a hand dynamometer, and "vital" capacity, as measured with a spirometer, are two of the oldest and most popular tests for what is vaguely described as physical fitness. Precisely what is measured in each case and what may be the significance of the measurements are questions still unanswered by the present monograph. It is, however, of value to examine the results of such measurements. Dr. Metheny's book is a critical review of previous work and an exhaustive presentation of findings in 206 children between the ages of $2\frac{1}{2}$ and $6\frac{1}{2}$. Correlations were computed for the relation of grip strength and vital capacity with various anthropometric measurements as well as with "health ratings," "fatigue ratings" and school absences. Values for normals, repeatability and change with growth are presented. Some slight relation between grip strength and "health" was noted, but vital capacity showed no such relation. There was also an indication that a decline in grip strength may precede the appearance of active infection of the upper respiratory tract. The present monograph is a record, in extenso, of meticulous observation and statistical computation. It is not likely to provide stimulating or even very informative reading to the average physician or scientist but should be invaluable to those few investigators who are seriously concerned about the details of simple grip strength and vital capacity tests. We may hope that factors such as the start of infection, which may produce sudden changes in grip strength, will be studied further and presented in more reasonable compass.

Medical Policies and Procedures for the Resident Staff of the Alameda County Hospitals and Clinics. Benjamin Warren Black, M.D., Medical Director of Alameda County. New edition. Cloth. Pp. 123. Oakland, California, 1941.

This manual is well abreast of modern practice, having been revised annually since its first publication in 1936. It is conveniently arranged in loose-leaf form with eighteen chapters covering general hospital information and instruction to the resident staff as regards the admission of patients, laboratory and x-ray service, clinical photography, anesthesia, accidents and emergencies, and the general management of individual clinical departments, including isolation and psychiatry. Suitable reference is made to the use of the sulfonamide drugs, the administration of parenteral fluids, transfusions, vitamin therapy and other special procedures, and a section of twelve pages devoted to the symptoms and treatment of poisoning gives information that is exceedingly valuable to the intern and resident staff. There is likewise a convenient index of medical procedures and a list of the drugs and preparations available in the hospital pharmacy. This handbook of medical and administrative procedures prepared by a physician prominent in the field of hospital administration might well be used as a model for other institutions planning to establish new rules or modify existing regulations appertaining to the house staff.

The Rockefeller Foundation, International Health Division, Annual Report 1940. Paper. Pp. 247, with illustrations, New York, [n. d.].

Each year the International Health Division of the Rockefeller Foundation publishes an annual report with information on the technical side of its work and with references to descriptions of its research work presented in the medical literature. The report is purported to be prepared for the health officer, the

public health student and readers interested in preventive medicine. Of the one hundred and fifty-two references analyzed and reported in the present edition, fifty-two relate to malaria and thirty-two to influenza. The contents of this annual report include an introductory statement covering the general activities of the division, a section on virus studies, a description of work on the control and investigation of specific diseases which include yellow fever, influenza, tuberculosis, syphilis, rabies, malaria, schistosomiasis, hookworm anemia, the common cold, scarlet fever, typhus fever, mental hygiene and nutrition, a summary of aid given to state and local health services, a description of the division's support to public health education, and a detailed account of expenditures. A table of contents together with an exceptionally adequate index provide a source of ready reference to the contents of this report. For a rapid perusal of the activities and studies undertaken by the staff of the International Health Division of the Rockefeller Foundation, this report offers a concise and clear source of reading. While the booklet will mainly appeal to those who are engaged in public health work, it contains many references of such international interest that no one will regret the time spent in passing over the pages.

When to See Your Doctor. By Robert S. Srigley, M.D. Paper. Price, 35 cents. Pp. 44, with illustrations. Columbus: College Book Company, 1941.

This pamphlet contains eight chapters dealing respectively with pneumonia, cancer, appendicitis, intestinal obstruction, diabetes, pulmonary tuberculosis, syphilis and heart disease. These chapters have been reviewed prior to publication by eminent physicians. Nevertheless the reviewer considers the treatment sketchy and inadequate. The title of the booklet, "When to See Your Doctor," taken in conjunction with the table of contents listing eight diseases, implies that only in these diseases does the author recommend seeing the doctor. The approach tends to favor self diagnosis, whereas the patient should be made conscious only of his own experiences which he can readily observe, even though he cannot interpret them. It is difficult to see how this booklet can contribute anything to the average patient's ability to decide when he ought to see his doctor and when he can safely procrastinate in the hope of spontaneous recovery.

A Text-Book of Bacteriology. By R. W. Fairbrother, D.Sc., M.D., M.R.C.P., Director of the Clinical Laboratory, Manchester Royal Infirmary, Manchester. Third edition. Cloth. Price, \$5. Pp. 451, with 6 illustrations. St. Louis: C. V. Mosby Company, 1941.

An introduction to this book has been written by F. E. Colien of Creighton University School of Medicine. The book is divided into three parts. Part 1 concerns general bacteriology and consists of twelve chapters; part 2 deals with systematic bacteriology and considers the specific infectious agents, which are discussed in twenty-two chapters; part 3 concerns general technic, which is considered in three chapters. The author has omitted the word "medical" from the title of this edition, since the book has been used by junior students of bacteriology in faculties other than those of medicine although the author primarily intended it for the medical student. There is no bibliography given, which makes the book useless as a reference guide. The illustrations are good and the tables are concise and very useful to the student in differentiating infectious agents. The book should prove useful to the medical student.

Roentgen Technique. By Clyde McNeill, M.D. Second edition. Cloth. Price, \$5. Pp. 329, with 276 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

The second edition of this treatise on roentgen anatomy and positioning is clearly designed for the physician, not for the x-ray technician. There has been added even more diagnostic material, and descriptions of technical procedures, which should be performed only by a physician, are a prominent feature. In an admirably concise style the author describes such relatively new x-ray methods as fluorography, body section roentgenography and cholangiography. The present edition also contains a section on fluoroscopy with particular attention to the dangers of this procedure. The methods of fluoroscopic localization of foreign bodies are well described. Pineal localization, pelvic and cephalic measurements, roentgen kymography and bronchography are treated in some detail. The additions and changes have increased the utility of the book. Its greatest value lies in the accurate manner in which x-ray positioning of all anatomic parts is described and illustrated.

Queries and Minor Notes

THE ANSWERS WERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VITAMINS AND COLDS

To the Editor:—Could you give me some advice regarding the advisability of giving vitamin preparations to industrial workers for the prevention of colds? Has there been any authoritative work done which indicates that any of the vitamins given to large numbers of workers will materially reduce the incidence of infections of the respiratory tract?

M.B., Toronto, Canada.

ANSWER.—Some work has been done on the relation of vitamin A to colds and to other infections of the respiratory tract. None of the other vitamins have been extensively tried, doubtless because there is no reason to suspect that they might be of any value. The evidence so far available shows clearly that administration of vitamin A or vitamins A and D combined has no beneficial effect in reducing the incidence of colds. There is some evidence, but it is not at all conclusive, that the administration of vitamin A, while it does not protect against colds, does seem to lessen the severity of the attacks. The evidence is not conclusive enough to justify any claim that administration of vitamin A would be of benefit in preventing colds or other infections of the respiratory tract.

ABSORPTION AND EXCRETION OF MERCURY

To the Editor:—A man was treated for syphilis over a period of several months with mercury inunction and some mercuric cyanide intravenously. He later suffered first and second degree burns over parts of his upper torso, and he died about twenty hours later. Postmortem examination showed 8 to 10 grains (about 0.6 Gm.) of metallic mercury in his liver and kidneys. He had had no mercury for several months prior to death. I wish to get all the available information as to the length of time mercury will remain in the tissues of the body after treatment is suspended.

H. S. J. Walker, M.D., Mobile, Ala.

ANSWER.—It is unfortunate that more complete data are not furnished as to the amount and dosage of the mercury inunctions and of the injections.

After intravenous mercurial injections the metal not excreted will consist of two parts: (a) the portion still circulating in the blood stream and (b) mercury that is stored. The circulating mercury reaches its peak level within a matter of hours or certainly days after an intravenous injection of the cyanide or of the oxycyanate, so that several months later any residuum would be found only as stored metal in various organs, principally in the kidneys and liver.

With mercurial inunctions, much of the ointment that is rubbed on is never absorbed, as it is only the portion that is rubbed into the hair follicles that is absorbed and of course this only slowly. It is for this reason that the recommendation has always been made with inunctions that the patient should keep rubbing for thirty minutes by the clock. Even then much of the ointment will be left on the skin, and the physician is never sure just how much has been absorbed. Moreover, the absorption after mercury inunctions is much slower than after intravenous injections of a soluble mercury salt.

Cole, Sollmann and Schreiber compared the urinary mercurial excretion after daily intramuscular injections of mercury sodium bromide (5.5 mg. of metallic mercury) with 4 Gm. daily inunctions of strong mercurial ointment (50 per cent of metallic mercury). At the end of the first week excretion of mercury in the inunction patients was one-half that in the patients on injections. At the end of the second week the level of excretion was about the same. At the end of four weeks excretion in the inunction patients was twice as much. This indicates the slow absorption of the fine globules of mercury from the hair follicles. So that excretion in an inunction case continues at a high level for at least a week after therapy is stopped and in 1 case there was a daily excretion of 0.3 mg. fifty days after all inunctions had been stopped.

However, these are small amounts, and it is understood that the patient in question had had no treatment for several months prior to death.

It certainly would not be possible for a man to live and go about his daily duties for several months with 8 to 10 grains of metallic mercury in his body. Lomholt (Quecksilber, Theoretisches, Chemisches und Experimentelles, *Handb. d. Haut- und Geschlechtskr.* 18:1, 1928) thinks that the saturation of

mercury that may be reached in the body without harm would be around 100 mg. (less than 2 grains). It would seem that some other source must be looked for to explain such a large amount of mercury as was found in this patient.

SULFANILAMIDE DERIVATIVES AND URINARY CRYSTALS

To the Editor:—Is there any drug which may be given a patient with bronchiectasis who is taking sulfathiazole that will prevent the appearance of crystals in the urine? Edward K. Disney, M.D., Tucson, Ariz.

ANSWER.—The appearance of crystals in the urine of a patient who is receiving sulfapyridine, sulfathiazole or sulfadiazine is not of special significance unless the crystals are accompanied by microscopic or macroscopic hematuria. It is to be remembered that in patients receiving moderate to large doses of one of these drugs the urine is liable to be saturated or even supersaturated with the drug, and hence crystals may be seen in freshly voided specimens of urine. If such saturated specimens of urine are placed in the cold, as almost always takes place in hospitals where the early morning urine specimen is placed in an ice box and allowed to remain there for several hours before being examined, crystals of the acetylated or free form of the drug can almost always be found and of course are of little significance. Recently, Schwartz and his co-workers (*THE JOURNAL*, Aug. 16, 1941, p. 514) have reported that the administration of sodium bicarbonate in amounts equal to that of the drug (sulfathiazole) being prescribed reduced the number of instances in which crystals appeared in the urine and also, apparently, the number of crystals of this drug in the urine. While it is not a good practice routinely to administer sodium bicarbonate with sulfapyridine, sulfathiazole or sulfadiazine, it would appear from the work of Schwartz and his associates that under certain conditions the maintenance of high alkalinity of the urine will decrease the amount of crystals in it.

PROBLEMS IN TREATMENT OF SYPHILIS IN FAMILY

To the Editor:—A man aged 32 has been found to have neurosyphilis, probably a brain gumma, with a history of primary infection seven years ago; he took a few treatments and then got married. He has a child 6 years old, another 3 years and another 8 months. A Wassermann test on the mother shortly before the 8 months baby was born was 4 plus (taken elsewhere); she received a few treatments before the child was born. Wassermann tests on the mother now are negative; so are they on the 8 months child and the 3 year old child. The 6 year old child is 4 plus. How can one account for this and what procedure should I take? Of course the mother should have a spinal fluid Wassermann test, but should the two negative children? Should these three be treated anyway or should one wait a while and take more Wassermann tests? If to treat them, how should it be done? Should one start the 6 year old girl on neosarsphenamine, sulfarsphenamine or bismuth and mercury preparations? The father is on iodides and a bismuth preparation now. After a course of this, it was felt that he should have fever therapy, probably by malarial inoculation. Would this be the proper procedure to follow in his case? This man also gave a transfusion one year ago to a 10 year old girl suffering with acute osteomyelitis. A Wassermann test taken by this girl now is 4 plus. Her osteomyelitis has never satisfactorily cleared up, and could this not be the reason? Also what treatment should one start her on? M.D., Iowa.

ANSWER.—In regard to the mother: The fact that her serologic reaction is positive and her oldest child also has positive serologic tests indicates, of course, that she has syphilis. The other two children apparently do not have syphilis, if there is no clinical evidence of the disease in them and their serologic tests are negative. Not every child born of a syphilitic mother necessarily has syphilis; in fact, about one half of the children born to syphilitic women will not have the disease. This can best be explained by the fact that *Spirochaeta pallida* did not pass through the placenta to the fetus, probably because the mother had developed a latent phase of syphilis and had few, if any, spirochetes in her blood stream. It does not seem necessary to make a spinal fluid examination of the two negative children, but it would be advisable to repeat the serologic tests of the blood at six month intervals for several years. The mother and the oldest child should have spinal fluid examinations.

The two younger children do not need treatment unless they should manifest in the future signs of or a positive serologic test for syphilis. The mother and child should be treated by

the so called continuous system with mapharsen and a bismuth compound, the mother to receive increasing doses of mapharsen from 0.01 to 0.04 Gm at five to seven day intervals for eight injections, while the child is given the same drug with dosage of from 0.005 to 0.02 Gm. The bismuth course should follow the mapharsen 1 cc being given four days to the mother and 0.5 cc to the child for a series of sixteen injections of bismuth, at the completion of this, the second course of mapharsen may be started. This program is continued until four courses of mapharsen and six courses of bismuth have been given.

The treatment of the father is dependent on the response he manifests clinically as well as in the spinal fluid to chemotherapy. If after a fair trial that is two courses of an arsenphenamine and bismuth, improvement is not obvious, fever therapy should receive serious consideration.

The osteomyelitis may or may not be of syphilitic origin, and the child's infection may be either congenital or acquired. A decision in this regard is impossible on the data presented and might require further examination. Not infrequently a syphilitic osteomyelitis will fail to heal under antisyphilitic treatment because the bony sequestrum remains and acts as a foreign body. An x-ray examination following antisyphilitic treatment should determine whether a sequestrum is present and whether its surgical removal is indicated. If the child has not been treated she may be placed on a program as just outlined for the child with syphilis.

NONTROPICAL SPRUE

To the Editor—What is the treatment at the present time for nontropical sprue and how does the disease vary from the tropical form? I have been using reticulogen and a fat free diet, but I cannot seem to stop the gradual weight loss which is occurring. Are any of the bile salts of use in the disease?

M D, New York

ANSWER—Tropical or endemic sprue is a chronic afebrile diarrhea occurring in rather limited tropical or subtropical areas and characterized by interference with intestinal absorption resulting in chronic starvation and wasting. The basic pathologic condition is one of nutritional deficiency gradually producing functional and then organic changes. The original deficiency is conditioned by other interwoven deficiencies, by infection and by various physiologic factors, such as in the endocrine system. The peculiar endemic distribution is unexplained. The classic symptomatic and clinical pathologic features rest primarily on a state of chronic starvation.

Nontropical sprue differs in having a nonendemic distribution, usually a more serious course and prognosis, a greater tendency to hemorrhage and much greater resistance to treatment methods which are highly effective in true or endemic sprue. Many consider the two conditions identical. Many others believe they are closely related, perhaps overlapping in etiology, but sufficiently distinct to constitute two different syndromes. Neither has an exact and invariable clinical picture, and in neither are exact pathognomonic criteria of diagnosis available.

Endless discussion goes on as to the relation of sprue to nontropical sprue, celiac disease, chronic pancreatitis, combined system disease of the cord, pellagra and pernicious (Addison-Biermer) anemia.

The principles of treatment in nontropical sprue are the same as for endemic sprue. They may be outlined as follows:

- 1 Diet should omit all sugar and reduce starch to a minimum. It should be primarily high in protein. N. H. Fairley's formula starts with a food ratio of protein 1, fat 0.3 and carbohydrate 1.3. With improvement this is gradually increased to protein 1, fat 0.36 and carbohydrate 2.0. Free use should be made of ripe bananas, banana flour, strawberries, whole fresh milk or goat's milk, beef juice and rare beef and such fruits as papaya if available.
- 2 Unconcentrated (old) liver extract should be given intramuscularly 5 to 10 cc daily for twenty to forty days.
- 3 When hydrochloric acid is decreased in the gastric juice, diluted (U. S. P.) hydrochloric acid should be given 4 cc in a glass of whole milk with each meal.
- 4 Vitamins B₁, B₂ and D should be given in large quantities by mouth. If ascorbic acid is below normal in the blood, it should be given, 25 to 50 mg, in the vein.
- 5 Calcium should be supplied as dicalcium phosphate or basic calcium triple phosphate, 12 Gm daily by mouth. Kaolin and bismuth subcarbonate may be added for severe diarrhea.
- 6 For flatulence, hot stupes, very hot baths and repeated small doses of castor oil (2-4 cc) can be used.
- 7 Mild sedatives are often needed. Iron preparations such as iron and ammonium citrates 0.5 Gm thrice daily are often needed to complete cure of the anemia. Repeated blood transfusions are often most beneficial. Bile salts are used in moderate dosage in the hope of improving intestinal absorption.

CHRONIC MYELOGENOUS LEUKEMIA AND PREGNANCY

To the Editor—A primipara aged 38, married sixteen years, has a normal menstrual history of five day duration with but little pain. There have been no miscarriages. She is a heavy set type about 5 feet 5 inches (165 cm) tall and has a normal weight of 138 pounds (62.6 Kg). Her past history is essentially negative. In April 1939, she had an ulcer on the anterior aspect of the left tibia. After several office treatments without improvement a biopsy was made and the pathologist reported a cutaneous cancer. This cancer was removed by the paste method the wound apparently has healed, and there do not seem to be any bad effects. In June 1941, fifteen months later, the patient noticed that her feet were swelling and that she had considerable abdominal distress. She also complained of being tired and described her condition as a sort of indigestion, which lasted for several months. In September, about four months later, a swelling occurred at the point of the navel. After her physician observed this for several days, he diagnosed an abscess, which he opened in the office. Immediately a severe hemorrhage occurred. As it was impossible to control the bleeding at the office, the patient was taken to the hospital and given an anesthetic. Many sutures were put in the abdominal wall around the incision to get the bleeding stopped. The perplexing question as to why the patient should bleed so profusely arose at once, and, after a careful examination and blood checking it was found that she was suffering from splenomyelogenous leukemia. Immediately roentgen treatments were administered to the spleen, and various blood counts were taken from time to time. The treatments have considerably reduced the white blood cell count. The patient has been taking a liver-stomach concentrate with iron and vitamin B complex by mouth, as well as liver hypoderemics, and a general improvement has been noticed in her condition. She feels well and does all of her home work. About a year later, April 15, 1941, was the last day of her normal menstrual period and she received several roentgen treatments of the spleen at this time. In May and June, when she did not menstruate, she was advised by the doctor who gave her the roentgen treatments that it was probably the treatments that had caused the cessation of the menses. After missing two periods she came to my office, June 15, 1941, weighing 141 pounds (64 Kg), the blood pressure 125 systolic and 70 diastolic, the Kolmer and Kahn reactions negative, the urine normal and much pleased with her general well being. I found her pregnant. She asked me if a pregnancy would have any bearing on a splenomyelogenous leukemia. In August the blood pressure and urine were normal and she had a 4 pound (1.8 Kg) increase in weight but was still feeling fine. When she plays golf or exerts somewhat she has a pinkish vaginal discharge, and, of course, she was advised to give up golf and be more careful. On August 14 (four and one half months after her normal menstrual period) she felt motion for the first time. The question of treatment of the patient and the prognosis are perplexing. Should the patient be given a chance at normal labor provided she has a normal course to the time of expectancy or should she have a cesarean section performed a short time before expectancy? Will continued roentgen treatment, which seems to be necessary to keep the white blood cell count down, cause unfavorable reaction to the fetus, and will it have any effect on the well being of the fetus? Would the administration of snake venom, vitamin K, congo red or the like be of any benefit to the patient before labor?

G C Bates, M D, Independence, Kan

ANSWER—In chronic myelogenous leukemia of this type, pregnancy may be allowed to proceed to its normal termination with the expectancy of a perfectly normal child. If roentgen treatment is given during pregnancy the child may be adversely affected, although there is a possibility that it may escape injury. In this case the fetus was between 4 and 6 weeks old when 120 roentgens were given, presumably over a remote region. It is probable that no damage was done, although it is impossible to predict absolutely. Roentgen therapy should be avoided and should not be given just because the leukocyte count is moderately high (25,000 to 50,000). Pregnancy alone, apparently, does not affect the course of the chronic form of the disease adversely, but the disease may be aggravated by premature termination of the pregnancy. The main problem is hemorrhage during delivery. Bleeding in chronic myelogenous leukemia is due mainly to the inadequate clot formation as a result of the excess of leukocytes. This condition is not influenced by the ordinary hemostatics but responds only when the leukocyte count is reduced by roentgen therapy before delivery. If the count can be reduced by treatment over the chest or spleen, the desired result may be obtained but the child may be injured. The same danger of hemorrhage is present, however, when cesarean section is attempted. Prophylactically, transfusions of 500 cc of human serum may be given intravenously just before delivery. If it is necessary to give intensive roentgen therapy during the course of the disease, the pregnancy must be terminated prematurely.

POSSIBLE LATE MENOPAUSAL SYMPTOMS

To the Editor:—A woman in her sixties, long past the menopause, says that she has had "hot flashes" several times a day for the last thirty years. These attacks are becoming more frequent and are preceded by a period of profound depression. The latter is more distressing to the patient than the hot flashes. There are no positive physical findings. Is there anything beside estrogenic hormones, which I am trying, that would make the vasomotor system any more stable?

George C. Christie, M.D., Canon City, Colo.

ANSWER.—While the duration of the vasomotor symptoms of the menopause, like their severity, is variable, such symptoms are rarely troublesome beyond a period of a few years, but in diminishing form they may continue longer. The term "hot flashes" refers to the hot, tingling sensations which often involve the whole body. The much more frequent "hot flushes" involve chiefly the head, neck and upper thorax, and it is possible that it is these of which the patient complains. There is general agreement that the entire group of vasomotor symptoms, including the characteristic sweats with the two already mentioned, is brought about by withdrawal of the estrogenic ovarian secretion, with consequent disruption of the reciprocal relations between ovarian and pituitary function. Aside from other evidence, symptoms of a second menopause have been noted in old women after the removal of the estrogen-producing granulosa-cell types of ovarian tumor (Novak, Schulze, Dworzak).

Moreover, it is now known that estrogen is produced in the bodies of at least a proportion of postmenopausal or even castrated women. The exact source of this production is not known, but the evidence points to one of the other endocrine glands, probably the adrenal cortex. In any event, such estrogen production in women well beyond the menopause might be expected to bring about phases of ovarian-pituitary disharmony not unlike that characterizing the menopause.

In the management of such cases, it is of prime importance to eliminate other possible causative factors. Chief among these is the neuropsychogenic element which so often confuses the picture of the normal menopause. It must be remembered too that somewhat similar vasomotor symptoms may occur in hyperthyroidism and in cases of so-called vasomotor instability. If practicable, studies of the vaginal smear and of the estrogenic and gonadotropic content of the urine may throw light on the problem in this case. The fact that the patient in question has apparently not responded to estrogenic treatment would suggest that they may not be of endocrine origin. On the other hand, perhaps the dosage has been insufficient. Menopausal symptoms of moderate severity would ordinarily be alleviated by doses of 10,000 international units given intramuscularly two or three times a week for from one or two to three or four injections. While other plans of treatment, such as irradiation of the ovary and hypophysis, have been suggested, they are, in the opinion of most gynecologists, associated with some hazard and are often ineffectual. For discussions of the general subject of menopausal therapy, including a consideration of dosage and routes of administration of estrogen, the possible hazards of overtreatment and the use of such nonhormonal estrogens as diethylstilbestrol, the correspondent may be referred to the following among many publications:

Shorr, Ephraim: The Menopause, *Bull. New York Acad. Med.* 16: 453 (July) 1940.

RED BLOTCHES OF SKIN IN CONGESTIVE HEART FAILURE

To the Editor:—Recently I have had several patients with congestive heart failure who in the last few weeks had small red blotches over the body. They began as small areas and rapidly increased in number and size. The patients died soon after. The condition might be called morbus maculosus. Could you tell me what the underlying cause is, increased venous blood pressure, increased permeability of the capillaries or changes in the carbon dioxide and oxygen in the blood?

Elmer E. Kottke, M.D., Des Moines, Iowa.

ANSWER.—It is uncommon for congestive heart failure to be attended during the last few days or weeks of life with macular skin lesions such as those described. No one consulted has been willing to attribute such lesions to congestive heart failure per se. Purpura can sometimes be terminal, that is, in the last few hours of life, especially in the presence of abnormalities of the blood or of the blood vessels when increased permeability of the capillaries may be largely blamed. Of course, in conditions such as subacute bacterial endocarditis or active rheumatism, cutaneous lesions are not uncommon, but they are not merely terminal and they are not primarily due to congestive heart failure. Hence the presence of red blotches over the body in the presence of congestive heart failure demands a search for some cause other than the heart disease and failure themselves.

HEMORRHAGE, SHOCK AND NIKETHAMIDE DOSAGE

To the Editor:—Can you tell me whether there is danger from an overdose of nikethamide in the agonized patient? A woman apparently in agony received caffeine and nikethamide subcutaneously one hour after the transfusion of 300 cc. of blood and 1,000 cc. of 5 per cent dextrose solution. Later I gave her nikethamide slowly intravenously. As long as the drug was being administered, the pulse and the respiration remained fairly good, although consciousness was not regained. After 6 ampules had been given I stopped the administration of nikethamide because (1) it apparently prolonged agony without returning the patient to consciousness and (2) I was afraid of an eventual overdose. Soon the patient died. There was a bleeding ulcer of the duodenum, confirmed by autopsy. Can you tell me whether agony in itself, loss of consciousness, exophthalmos, deep, suffocated breathing and small quick pulse is a reversible condition, and how long it is reversible? Does it represent irreparable damage of the cortex of the brain or not? The postmortem examination of the patient, which showed the bowels full of blood, raises the third question: As all life-saving measures tend in themselves to raise blood pressure and increase bleeding, do you think it advisable to operate on such a patient? When the patient entered the hospital the hemoglobin content was 50 per cent.

M.D., Oregon.

ANSWER.—There is little danger of overdosage of nikethamide as the toxicity is low and the substance is rapidly detoxified in the body. Overdosage is conditioned not only on the size of the dose but on the rapidity with which the drug is given. The drug carries its own warning signal, as it becomes a convulsant before the lethal dose is approached.

The patient probably had a peripheral vascular collapse. When this occurs there is a deficient return flow to the heart. This deficient return flow comes about (1) when blood escapes from the vessels, (2) when plasma escapes into the tissues and (3) when the arteriolar bed dilates or blood collects in the viscera. In this case there was probably a combination of escape of blood from the hemorrhage from the ulcer and collection of blood in the viscera from a dilatation of the arteriolar bed. The result would be a tremendous fall in blood pressure and a diminished cardiac output. The hypotension and deficient cardiac output are accompanied by a deficient cerebral and coronary blood flow. If the blood flow in the cerebral and coronary circulation is deficient over a long enough time irreparable damage ensues and the condition is irreversible. If the collapse is overcome either by restoration of the vasomotor tone or by control of the hemorrhage, before irreparable damage ensues, the patient recovers. In cases of severe collapse it is often impossible to tell from the clinical symptoms whether the condition is reversible. In this case it seems fair to assume that the vasomotor tone was partially restored but the blood loss continued.

The question of operation requires the exhibition of most critical judgment. As a general proposition, the presence of shock or peripheral collapse is a contraindication to operation. Surgical shock added to peripheral collapse is likely to be fatal. It is conceivable that if bleeding were known to be going on and its source were known an attempt to stop the hemorrhage might be made. It seems more than likely that in the situation described the patient would have succumbed in any event.

SPASMODIC TORTICOLLIS

To the Editor:—Can you give me the consensus as to the operative results of section of the eleventh cranial nerve for so-called functional spasmodic torticollis? My patient has had severe spasms for the past four or five months. He has been examined by two neurologists, who agree that it comes under the heading of "functional spasmodic torticollis." Does simple crushing of the nerve as is performed in a temporary phrenic nerve paralysis offer any value?

M.D., New York.

ANSWER.—Since the cause of any one particular instance of spasmodic torticollis is seldom determined, adequate treatment may be lacking, and, in fact, any treatment of this condition may be and frequently is of little effect. That it may actually be on an organic basis and follow encephalitis, striatal disease or myositis seems entirely tenable. However, in most instances the condition is believed to be on a functional basis, and by far the larger number of such patients are helped by intelligent psychotherapy. Since in the usual case of torticollis many more muscles than the sternocleidomastoid are involved, it is not sufficient to cut the accessory nerve alone to arrest the spasms. This procedure has, by and large, been marked with failure, and crushing the nerve would not be recommended as either rational or useful. Some surgeons have, with moderate success, cut the posterior roots of the upper cervical cord, together with the accessory nerve on the involved side. Others have gone so far as to cut the anterior and posterior roots of the cervical cord, together with the accessory nerve on both sides, thereby destroying all efferent and afferent pathways of the cervical musculature. Then, of course, the neck could not be moved even by a hysterical person, but such radical surgery would seem to be

rarely if ever recommended. Operative results for spasmodic torticollis are poor, psychotherapy is the best means of treatment of the usual patient with this complaint, many cases will not respond to treatment of any kind.

SUBLUXATION OF RIB FROM LIFTING AND ABDOMINAL PAIN

To the Editor—While lifting a 90 pound roll of wire, a white man aged 35 suddenly experienced a severe pain in the back just to the right of the spine, over the twelfth rib. The past medical history is negative, there had been no previous back injury, and the patient is accustomed to handling objects weighing as much as 200 pounds. The pain was immediately relieved with diathermy but returned one hour later and required opiates. Twenty four hours later he had sudden severe epigastric pain with generalized boardlike rigidity of the abdomen. Roentgenograms of the chest and abdomen were negative, roentgenograms of the thoracic spine revealed a slight separation of the twelfth right rib from the spinal attachment, the white blood count was 13,000 with 90 per cent polymorphonuclears, the temperature was 100.8 F, urinalysis was negative, the blood Wassermann and Kahn reactions were negative, and the pulse was 72, full and regular. In view of the history of injury it was decided to treat the patient conservatively, and the following day his condition remained unchanged with the exception of occasional emesis of undigested food and bile, his morning white blood count was 20,000, dropping to 10,000 by evening. Infusion of 5 per cent dextrose solution was followed by a chill and a temperature of 104 F. Three hours later his temperature dropped to 100 F, and the pain and rigidity disappeared from the abdomen. The following morning the patient was comfortable except for pain in the back, and he has continued to improve daily. Surgical consultation was called with the development of the epigastric pain, and the surgeon felt that there was probably a coincidental perforated ulcer which had sealed off. I should like to know whether the rapid improvement of abdominal symptoms is compatible with such a diagnosis and whether this severe epigastric pain could be due to an injured intercostal nerve or a diaphragmatic injury even though the roentgenograms of the diaphragmatic area were negative.

M D, Iowa

ANSWER—After consideration of the evidence given in this case there is no hesitation in stating that such a train of symptoms as detailed in the report could not come from a subluxation of so small a joint as the twelfth rib. The patient might have a little local tenderness which would last a varying length of time, but the other symptoms would not be present. This man probably had one of three conditions in the abdomen. 1 A perforating ulcer is possible which sealed itself over. In a flat chested man with the liver pressed closely down over the duodenum one of these perforations can be shut off and walled in with great rapidity. 2 If the patient had a barrel shaped chest, one would have to seek another explanation. In this type of individual one would suspect an acute cholecystitis with an obstruction of the cystic duct of a ball valve type which relaxed and permitted a free flow of bile, thus relieving the symptoms. 3 The third possibility would be an acute appendicitis of an obstructive type in which the obstruction is relieved and the inflammatory mass empties into the bowel. Either of the conditions detailed in 2 and 3 could give the symptom complex as shown in the report. The speed of repair and convalescence following 2 and 3 would be far more rapid than in 1.

THERAPY OF HYPOPARATHYROIDISM

To the Editor—A woman who had a thyroidectomy about five years ago has received oral calcium and parathyroid since the operation. Without the calcium she quickly develops signs of hypothyroidism with tetany. For the past two months the parathyroid has not seemed to work, and it has been necessary to give calcium intravenously in order to maintain the blood calcium anywhere near normal. Calcium gluconate intravenously in her case does not give as complete relief from symptoms as calcium chloride intravenously, which is being used at present. This, of course, reduces the heart rate to less than 50 at the time of administration. The patient also has hypertension and chronic gallbladder disease. I should like to know as to the advisability of continuing the use of the intravenous calcium chloride over a long period of time, whether or not it is contraindicated, and any suggestion as to therapy if it becomes necessary to discontinue this form of therapy.

J F Rommel, M D, Oneida, N Y

ANSWER—The therapy of hypoparathyroidism is now simple and satisfactory. The intravenous administration of calcium salts is no longer necessary except in an acute emergency. Then calcium gluconate is preferable to calcium chloride, since it is less irritating. Dihydroxycholesterol is capable, when administered by mouth, of raising the serum calcium value to normal and thus of overcoming most of the symptoms of hypoparathyroidism. One usually starts with 5 mg of this substance daily for about five days and later reduces the dosage to 5 mg three times a week. The only danger to keep in mind is the possibility of producing hypercalcemia. This danger has been overemphasized in the past, however. It may be guarded against by doing rough tests for calcium in the urine with the use of the Sulkowitch reagent. Further details are given by Fuller Albright (Note on the Management of Hypoparathyroidism with Dihydroxycholesterol. *THE JOURNAL* June 24, 1939, p 2592).

PROBABLE SCLEROSING OSTEITIS OF GARRE

To the Editor—A man in his thirties who was operated on one year ago for acute osteomyelitis of the femur has suffered from furunculosis for years. He states that *Staphylococcus albus* was isolated. At present he has a discharging sinus on the upper outer side of the thigh which necessitates the wearing and changing of daily dressings. At present the roentgenograms show fusiform thickening of the cortex of the upper third of the left femur just below the lesser and greater trochanters, more evident at the site of the lesser trochanter. This fusiform swelling is due to some irregular bone formation derived from the outer portion of the cortex and the periosteum. No evidence of sequestrum or cavities is seen. The findings indicate a chronic osteomyelitis of long standing. I have curetted the walls of the sinus and removed a valvlike membrane which obstructed the opening. The sinus is 1½ inches long. I packed it with sterile sulfanilamide daily for a week. At present I am packing the sinus with a drain saturated with azochloramid in olive oil 1:2,000 every four days. The discharge at present is seromucous. I should like to know how this sinus can be healed.

M D, New Bedford Mass

ANSWER—From the description of the roentgenograms it would seem that this condition might be due to an osteitis known as the sclerosing nonsuppurative type originally described by Garre. However the name is misleading for sometimes osteitis of this kind does break down and suppurate and drainage occurs but usually there is no sequestrum. If there is a sequestrum it is small. If there is no sequestrum and no central bone abscess in this case (which should be apparent in the roentgenogram if present), it might be well to try swabbing out the sinus every day with a solution of equal parts of phenol (carbolic acid) and tincture of iodine being careful to protect the skin edges with an alcohol pad while this is being done. Sometimes this solution will destroy the granulating tissues and scarify the sinus tract causing the walls to collapse and adhere and thus close the tract. If treating the condition in this manner every day for ten days or two weeks does not result in improvement the treatment should be discontinued. One might also try injecting the sinus tract with a solution of sulfathiazole and sesame oil. Sufficient sulfathiazole should be put in the sesame oil to produce a thick paste solution which can be injected into the sinus. This should be repeated daily for several weeks.

There is no royal road to the healing of sinuses due to osteomyelitis. The main point is to be certain that there is no dead bone present for if there is treatment will not produce results. Sequestrums must be removed or work their own way out.

PAINFUL PAROXYSMS OF JAW

To the Editor—A housewife aged 45, who has been known to have diabetes for the past eight years, has been taking insulin for only three months. 50 units daily and has the diabetes well controlled. About two months ago she had a set of dentures made and complained of no trouble until three weeks ago. Then suddenly she experienced excruciating pain in the lower jaw on taking the first bite at mealtime. The pain is bilateral and around the angle of the jaw, it does not radiate and is described as a severe shooting sensation. She has to grab her jaw with both hands until the sensation subsides. After the momentary pain subsides she can eat the remainder of the meal in comfort. Oddly enough fluids also produce the pain, which is not related, apparently to motion at the articulation, thus she gets the pain on taking orange or tomato juice, but milk, tea and coffee produce no ill effects. I sent her to a dentist to ascertain what role the new dentures might be playing as a cause of such pain. He thought that pressure on the long buccal nerve might be the cause and on infiltration with procaine hydrochloride the patient had complete though temporary relief. Accordingly the dentures were filed down to alter the bite somewhat, but the patient continues to look forward to each meal with dread because the pain continues unabated. I find this case so unusual that I write to ask your opinion and suggestions.

M D, New York

ANSWER—The data presented are not sufficient to permit a diagnosis in this case. The painful paroxysms are not typical of trisfacial neuralgia, and the diabetes probably has no direct etiologic bearing. While a change in the dental bite resulting from the dentures may have produced some alteration in the temporomaxillary articulations it is not likely that this has any direct bearing.

The character and distribution of the pain suggest a muscle spasm or a transitory obstruction of the parotid ducts. The latter is supported by the fact that fruit juices, which tend to stimulate profuse secretion of saliva induce the pain whereas bland fluids do not. It is possible that trauma or irritation to the meatuses of Stensen's ducts attributable to the dentures may have a direct causative effect.

In all probability the painful paroxysms will disappear spontaneously in the course of time, and leaving the dentures out for a while is likely to hasten this.

LOCALIZED YELLOW DISCOLORATION OF SKIN AND AMENORRHEA IN YOUNG WOMAN

To the Editor:—A young woman aged 17, well nourished and healthy looking, ceased to menstruate three years ago. All laboratory analyses were made and nothing abnormal was found; the blood chemistry was somewhat increased. Examination of the heart, lungs, pelvis and so on revealed no abnormalities. Psychically she seems somewhat deviated from the normal; there are spells of melancholy and excited states. She has had much estrogenic therapy by mouth and enterically with heavy dosage but so far to no effect. Her mind is much disturbed by the fact of menstruation not appearing. She has a peculiar icteric discoloration of the skin of the hands and feet only. The skin of the rest of the body is clear, as is the sclera of both eyes. There are no clay colored stools. Can you help me as to the cause of the color of the skin of her hands and feet and the probable cause of her lack of menstruation? The estrogenic products were of different reliable manufacture.

M.D., Iowa.

ANSWER.—It is presumed that the usual liver function tests have been performed and have failed to reveal liver damage. There is a possibility that the peculiar discoloration in this case is due to carotenemia rather than to a derangement in the liver or gallbladder. In cases of carotenemia there is rarely any discoloration of the conjunctiva but the change is localized elsewhere. Some obese women who are on a rigid diet eat an excessive amount of carrots and develop carotenemia. If this is true in this case, carrots should be omitted from the diet. Even if the patient is not consuming large amounts of carrots, it may be advisable to omit them for a while.

It is unfortunate that the tests failed to reveal any specific abnormality, because most likely in this case the persistent amenorrhea is due to some general disturbance. Estrogen therapy may produce bleeding but it will not be periodic unless the treatment is carried out repeatedly. This, of course, is not true menstruation. More logical therapy for the amenorrhea is the use of pituitary preparations or gonadotropic hormone from mare's serum, but both of these preparations yield successful results in only a small proportion of amenorrheic women.

YEAST INFECTION OF VAGINA IN PREGNANCY

To the Editor:—A patient pregnant about six months showed on antepartum examination a yeast infection of the vagina. There are always thick chunks of cheesy material present which, on microscopic examination, show the yeast organisms. I have treated the patient with compound solution of iodine and methylrosaniline with no result. Could this yeast infection produce a serious infection during the puerperium? How long do you think I should continue local treatment in this case? As a rule, I do not touch the vagina, if possible, during the last weeks of pregnancy. This patient otherwise is healthy. There is no sugar in the urine. Could you advise me what to do to get rid of this infection?

Ludwig Gruenewald, M.D., Sheboygan, Wis.

ANSWER.—Yeast infections of the vulva and vagina are more common in pregnant women than in the nonpregnant. In some pregnant women the condition persists despite treatment but disappears spontaneously soon after delivery. It may, however, reappear later. There need be little fear about puerperal infection arising from the yeast infection. Nevertheless the condition should be treated even during the last few weeks of pregnancy to give the patient relief from itching and other symptoms. In nearly all cases, temporary benefit can be obtained by thorough application of 1 to 2 per cent solution of methylrosaniline to all parts of the vulva and vagina. This treatment should be carried out every second day for four or five times or until the discharge and its symptoms disappear. In some cases element iodine as found in 0.5 to 0.25 strength compound solution of iodine or 0.25 to 0.20 strength tincture of iodine is helpful.

SLOUGHING FROM SCLEROSING SOLUTIONS

To the Editor:—On two occasions after the injection of sodium morrhuate into a vein on the leg of a young unmarried woman there was a leakage into the surrounding tissues. Is this due to any peculiar porosity of the vein or is this drug more likely to filter through than some of the other drugs employed? Can you refer me to any literature bearing on these points?

M.D., Massachusetts.

ANSWER.—Perivenous infiltration or necrosis occurs following the injection of sclerosing solutions when the tip of the needle slips out of the vein or when the wall of the vein is infiltrated with the solution. Occasionally, however, a small area of sloughing may occur at a considerable distance from the site of injection, at a point where the wall of the vein is thin and closely adherent to the skin. In the presence of small, thin walled intracutaneous varicosities it is safer to use a 50 per cent dextrose or a 10 per cent sodium chlorite solution, because more active solutions may produce a necrosis of the wall. Further safeguards against sloughs following the injection treatment are the employment of fine, 23 to 25 gage, needles with

short bevels, a free flow of blood on aspiration and a continuous watch for edema or blanching around the vein during the injection. If the perivenous injection is promptly stopped and the area around the vein is infiltrated with procaine hydrochloride, physiologic solution of sodium chloride, or the patient's own blood, a cutaneous necrosis may often be averted.

A pamphlet of the American Medical Association on varicose veins, reprinted in 1940, gives more detailed information on the subject. It can be obtained on application.

MEDICINAL USES OF FLAXSEED

To the Editor:—Does flaxseed tea, used over a period of weeks or months, in amounts of 2 cups a day, have any irritating gastric effect, such as nausea or injurious action on the bowel? Does it leave an acid residue? I have been unable to find the answer to these questions in any books available to me. Can you advise where I might get a satisfactory treatise on flaxseed and its medicinal actions?

L. C. Mudd, M.D., San Francisco.

ANSWER.—Flaxseed, a synonym for linseed, is said to have the properties of a demulcent and emollient because of the mucilage and oil it contains. Although an infusion has in the past enjoyed varying popularity in the therapeutics of the respiratory and urinary tracts, present evidence indicates that any therapeutic value of linseed probably is confined to its use as an emollient poultice and as a demulcent. The daily use of dilute solutions of flaxseed "tea" should not cause any gastrointestinal irritation. It does not leave an acid residue. Sources of information on the Linum, U. S. P., and Linaceae (flax family) are:

Second Supplement to the Pharmacopoeia of the United States of America (U. S. P. XI, 1939 Supplement).
Mansfield, W. W.: *Materia Medica, Toxicology and Pharmacognosy*, St. Louis, C. V. Mosby Co., 1937.
Youngken, H. W.: *A Textbook of Pharmacognosy*, Philadelphia, P. Blakiston's Son & Co., 1936.
The Dispensary of the United States of America, Philadelphia, J. B. Lippincott Company, 1937.

The last named publication contains the following pertinent statement on the use of flaxseed: "There is a popular notion that the mucilaginous substances can be absorbed from the alimentary tract and exercise an internal demulcent action, and an infusion made by treating the whole seeds with boiling water is widely employed in catarrhs of the respiratory or urinary tracts. But as the gums, like other carbohydrates, are affected by digestive juices, no benefit is to be expected from such a use of the drug."

REPAIR OF THORACOTOMY WOUNDS

To the Editor:—Would you be kind enough to refer me to any articles on the plastic surgical repair of old deforming thoracotomy wounds?

Joseph L. Gaster, M.D., Brooklyn.

ANSWER.—A satisfactory article dealing with this subject has not been found. Plastic repair of deforming, completely healed thoracic wounds is rarely undertaken, partly because they may be covered by clothing and partly because the depression produced by the loss of ribs cannot adequately be overcome. Ugly, broad, depressed scars resulting from the healing of infected wounds may be excised, the extracostal muscle layer freed from binding scar tissue, and the muscles and skin sutured in separate layers. Primary union and a considerable improvement in the appearance of the wound may be expected if the suturing has been accomplished without tension.

Deforming, unhealed thoracic wounds, in the depth of which the lung and bronchial fistulas are exposed, present a complicated problem. When the lung is not the site of residual infection and when there is little or no wound discharge or sputum, the defect may be closed by pedicled grafts of muscle or skin. When infected, such closure cannot be effected until the pulmonary infection has been overcome either by the adequate drainage of residual abscesses, by the removal of bronchiectases by lobectomy or by other means.

VITAMINS AND DEAFNESS

To the Editor:—In the Oct. 25, 1941, issue of *The Journal*, page 1491, there is an answer to a question headed "Vitamins and Deafness." The answer contains a quotation at some length of comments made by Dr. George E. Shambaugh Jr. but leaves out an interesting discussion by H. E. Harris and P. R. Moore of the Grile Clinic, which appeared in the *Medical Clinics of North America* 24:533 (March) 1940. This discussion gives a quite different view of the subject than do the comments quoted from Shambaugh. I should like to point out also that I have never claimed that vitamins would completely restore loss of hearing caused by deafness due to eighth nerve involvement.

Grant Selfridge, M.D., San Francisco.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE

DEPARTMENT, JULY-DECEMBER, 1941

Titles have been listed or Abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1932. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "SS," Student Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2361.

A

A.T. 10: See Dihydrocholesterol
 ABBOTT-Miller Tube: See Colon, surgery, Intestines, surgery
 ABDOMEN: See also Gastrointestinal Tract; Pelvis; Peritoneum
 Adhesions: See Adhesions
 disease, Blumer's rectal shelf sign, [Bue & others] *167
 Distention: See Flatulence
 foreign body, gauze sponge, X-ray identify, 817
 hemorrhage: arterial apoplexy, [Beik] 317—ab; [Bunch] 648—ab
 pain and subluxation of rib from lifting, 2299
 pain, attacks of, 978
 pain (chronic) due to hypoglycemia, [Sandler] 71—ab
 pain in cyclic vomiting, [Karelitz] 2197—ab
 pain in rheumatic children, [Langmann] 361—ab
 pain (right lower recurrent), appendectomy for, [Warren & Ballantine] *994
 Rectal Abdominal Support, 1461—BI
 surgery, plastic removal of excess skin in obesity, [Short] *309
 tuberculosis in children, [Hairenstein] 1302—ab
 tumor, peritoneoscopy, [Garrey] 1390—ab
 wounds, gunshot, [Fukadal] 1474—ab
 ABNORMALITIES: See also Crippled; Ear; Extremal Defect; Lungs, absence; Thyroid; Uterus, double; etc.
 genetics of malformations, 1662
 ABORTION, incomplete, stick removal evacuation of uterus, 1750
 Infectious, in Cattle: See Brucellosis
 missed, treatment; indication for evacuating uterus, 1057
 prevalence of abortionists; physicians' false attitude, [Hamilton] 216—C
 racket, survey, New York, 1993
 repeated, corpus luteum plus vitamin E for, [Wenne] 2013—ab
 repeated, trauma cause of, 904
 ABRAMS, ALBERT, electronic reactions exploited, 1281—BI
 ABSCESS: See also Ulcer; and under organ affected
 peritonitis, and tonsillectomy, 817
 treatment, sulfanilamide, locally, [Long] 1121—ab
 ABSORBINE, Jr., 2188—BI
 ABSORPTION: See Mercury; Skin; Sulfanilamide and Derivatives
 ABYSSINIA: See Ethiopia
 ACACIA for nephrotic syndrome, [Goudsmit] 1918—ab; 2276—ab
 ACADEMY: See also American Academy, Cleveland; New York; Pennsylvania; Rochester; etc.
 of Medicine, Atlanta, new home, 206; (illustrated) 1548
 of Medicine of Northern New Jersey, Eagleton Medical Civic House, 1275
 ACARUS scabiei: See Scabies
 ACCIDENTS: See also Casualty Stations; Disability; Trauma; Wounds
 Automobile: See Automobiles
 Aviation: See Aviation
 fall (severe), complete heart block after, [Coffen] 647—ab
 fatal, rate in 1939, 209
 First Aid for: See First Aid
 home and farm, Red Cross hazard hunt, 2182
 housing conditions in relation to, 301—OS
 Industrial: See Industrial Accidents; Workmen's Compensation
 National Safety Council
 National Safety Council, 1363—E
 See also Automobile accidents
 traffic, alcohol and pedestrian in subway and "L" trains, etc., [Gonzales & Gettler] *1523
 traffic, Germany, 308
 traffic, slaughter on the roads, England, 803

ACETYL-Beta-Methylcholine: See Methylglycarsonobenzene, Millan's erythema from, [Peters] 1732—ab
 phenylhydrazine does not discolor teeth, 1058
 Sulfamide: See Sulfanilamide and Derivatives
 ACID, Amino Acids: See Amino Acids
 aminoacetic (glycine), effect on muscular strength, [Horvath] 2193—ab
 Ascorbic: See also Vitamin C
 ascorbic, detoxifying action in arsenical therapy, [Bundesen & others] *1692
 ascorbic, effect on wounds, [Tineas] 898—ab; [Lund] 2006—ab
 ascorbic, intravenously in acute hemorrhage, [Stewart] 1216—ab
 ascorbic, N.N.R. (Breon) 680; (Stearns) 680; (International Vitamin Corp) 1265; (S.M.A. Corporation) 1707
 ascorbic, treatment in compound fractures, [Agostinelli] 1299—ab
 Carbolic: See Phenol
 Cevalmic: See Acid, ascorbic
 deoxycholic, Degalol, (Council report) 361
 hyaluronic, Dorian-Reynolds "spreading factor," 1099—E; [Meyer] 1728—C
 Hydrochloric: See Stomach acidity
 liquid in cadmium-plated ice cube trays, poisoning from, [Frant & Kleeman] *86
 Nicotinic: See also Vitamins B
 nicotinic acid amide, N.N.R. (Merrell) 1265; (S.M.A.C.) 1707; (Breon) 2073
 nicotinic acid, N.N.R., (Merrell) 1707; (Endo) 2073; (I.V.C.) 2169
 nicotinic, and stomatitis aphthosa, [Damianovich] 1741—ab
 nicotinic, deficiency, encephalopathy, [Jolliffe] *1496, 2193—ab
 nicotinic, distribution in foods, 197—E; [Ruffin] *1495
 nicotinic, dosage recommended, [Ruffin] *1495
 nicotinic, treatment of deafness (Selfridge's), 1491, (reply) [Selfridge] 2300
 nicotinic, treatment of psychiatric disorders, [Sydenstricker] 1465—ab
 pantothenic, for alopecia totalis, 1752
 salicylic, Mester's test in rheumatism, [Cervia] 2198—ab
 thymonucleic, effect on erythrocyte sedimentation, [Moni] 491—ab
 ACID-BASE BALANCE, opium alkaloids effect on, [Ra] 1301—ab
 ACIDOSIS, Diabetic: See Diabetes Mellitus
 treatment, sodium L-lactate one sixth molar, 1445
 ACME Ointment Co., "pile remedy," 1375—BI
 ACNE: See also Furunculosis
 eruption in gasoline station attendant, 408
 etiologic role of androgens, [Hamilton] 1293—ab
 nostrum, Medix Ointment and Soap, 1727—BI
 occupational, [Jones] 1469—ab
 vulgaris: pustular lipodosis, low fat diet and thyroid extract for, [Sutton] 2103—ab
 vulgaris, sulfathiazole ointment for [Keeney & others] *1416
 ACOUSTICON, 1978
 ACQUA Fuggi and Fernet Vittone, 1643—BI
 ACQUIN, 1461—BI
 ACROCYANOSIS, impaired peripheral circulation in girl, 1221
 ACRODYNIA: See Erythredema
 Factor: See Pyridoxine
 ACTINOMYCES necrophorus: See Bacteria, Bacterium necrophorus
 ACTINOMYCOSIS, [Davis] 958—ab
 bronchial X-ray appearance, [Reeves] 391—ab
 pharyngeal, [Moriya] 1745—ab
 ACTIVANAD, 1805—BI
 ACTIVITY, early rising after operation, [Leit-hauser] 644—ab; 1710—E
 ACTORS, Dr. C. Wyndham a foremost comedian, 1930—SS

ACTUARIAL Society of America, BLOOD PRES-SURE Study, [Hunter] 62—C
 ADAPTATION: See Eyes, accommodation
 ADDICTION: See Alcoholism; Morphine; Narcotics; etc.
 ADDIS Count: See Urine
 ADDISON'S ANEMIA: See Anemia, Pernicious
 ADDISON'S DISEASE, treatment, adrenal hormones, [Hartman] *1407
 treatment, grafting adrenal, [Katz] 619—ab
 treatment; prognosis, [Hampton] 1290—ab
 treatment, subtotal hypophysectomy effect in, [Starr] 480—ab
 ADENTITIS: See Lymphatic System; Periladenitis
 ADENOCARCINOMA of thyroid and hyperthyroidism, [Friedell] 1568—ab
 of rectum, prognosis, in, 2202
 of small bowel, [Horsley] *2120
 ADENOFIBROMA, giant intracanalicular, of breast, [Owens] 2007—ab
 ADENOIDS obstruction vs impaired hearing, 370—E
 ADEMOMA, hyperplasia of adrenal cortex in essential hypertension, [Rinehart] 1118—ab
 Nontoxic, of Thyroid: See Goiter, nodular
 pancreatic, producing insulin (insulinomas), surgery for, [Windfeld] 972—ab
 Toxic, of Thyroid: See Goiter, Toxic
 ADENOMYOMA, pelvic, [Danneuthner] 66—ab
 uterine, [Randall] 2008—ab
 ADENOMYOSIS: See Endometriosis
 ADHESIONS, omental
 ADHESIVE plaster, minimize irritation caused by, [Legge] *1783
 ADIPOGENITAL Dystrophy: See Dystrophy
 ADLA Tablets, 1909—BI
 ADNEXITIS: See Uterus
 ADOLESCENCE: See also American Youth Commission, National Youth Administration
 auricular fibrillation in, [Gibson] *96
 cancer of cervix uteri in, [Bowling] 888—ab
 chlorosis, [Olef] 2009—ab
 convulsive state in high school girl, 1750
 gynecologic problems, [Novak] *1950
 health in Buenos Aires, 549
 medical rehabilitation program for, 1632
